Abstract

There are two fundamentally different approaches for specifying and verifying properties of systems. The *logical* approach makes use of specifications given as formulae of temporal or modal logics and relies on efficient model checking algorithms; the *behavioural* approach exploits various equivalence or refinement checking methods, provided the specifications are given in the same formalism as implementations.

In this paper we provide translations between the logical formalism of ν -calculus and the behavioural formalism of disjunctive modal transition systems. The translations preserve structural properties of the input specification and allow us to perform logical operations on the behavioural specifications as well as behavioural compositions on logical formulae. The unification of both approaches provides additional methods for component-based stepwise design.

Keywords: component-based design, refinement, logic, modal transition system, specification

1. Introduction

There are two fundamentally different approaches to specifying and verifying properties of systems. Firstly, the *logical* approach makes use of specifications given as formulae of temporal or modal logics and relies on efficient model checking algorithms. Secondly, the *behavioural* approach exploits various equivalence or refinement checking methods, provided the specifications are given in the same formalism as implementations.

[☆]This article is based on the conference papers [8, 26] which have been presented at the 24th International Conference on Concurrency Theory in Buenos Aires, Argentina, and at the 11th International Colloquium on Theoretical Aspects of Computing in Bucharest, Romania.

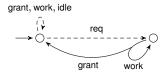

Figure 1: DMTS corresponding to the CTL property $AG(req \Rightarrow AX(work\ AW\ grant))$

Figure 2: An implementation of the specification in Fig. 1

In this paper, we discuss different specification formalisms and their relationship. As an example, let us consider labelled transition systems and the property that "at all time points after executing req, no idle nor further requests but only work is allowed until grant is executed". The property can be written in e.g. CTL [21] as

$$AG(req \Rightarrow AX(work AW grant))$$

(here "AW" denotes the weak-until operator) or as a recursive system of equations in Hennessy-Milner logic [42] as

$$X = [\mathsf{grant}, \mathsf{idle}, \mathsf{work}] X \wedge [\mathsf{req}] Y$$

$$Y = (\langle \mathsf{work} \rangle Y \vee \langle \mathsf{grant} \rangle X) \wedge [\mathsf{idle}, \mathsf{req}] \mathbf{ff}$$

where the solution is given by the greatest fixed point.

As formulae of modal logics can be difficult to read, some people prefer automata-based behavioural specifications to logical ones. One such behavioural specification formalism is the one of disjunctive modal transition systems (DMTS) [44]. Figure 1 displays a specification of our example property as a DMTS. Here the dashed arrows indicate that the transitions may or may not be present, while branching of the solid arrow indicates that at least one of the branches must be present in any correct implementation of the specification. An example of a labelled transition system that satisfies our logical specifications and implements the behavioural one is given in Fig. 2.

The choice between logical and behavioural specifications is not only a question of preference. Logical specification formalisms put a powerful logical language at the disposal of the user, and the logical approach to model checking [21, 50] has seen a lot of success and tool implementations. Automata-based specifications [17, 40], on the other hand, have a focus on *compositional* and *incremental* design. For a model consisting of several components, compositionality permits to (1) infer properties of a system from the specifications of its components, and (2) decompose the problem of correctness for a system into verification problems for its components, which helps in overcoming the state space explosion problem [2, 3, 41]. In this respect, logical specifications are somewhat lacking. Further, given a global property of a model and a component of the model that is already known to satisfy a local property, one would be able to *decompose* automatically, from the global property and the local property,

$$X = \langle a \rangle \mathbf{tt} \wedge [a] X \wedge [b] X$$

Figure 3: ν -calculus formula and DMTS for the invariance property "there is always an 'a' transition available", over the alphabet $\Sigma = \{a, b\}$

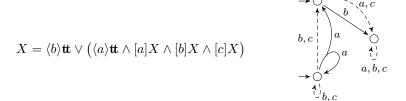

Figure 4: ν -calculus formula and DMTS for the ("weak until") property "there is always an 'a' transition available, until a 'b' transition becomes enabled", over the alphabet $\Sigma = \{a, b, c\}$

a new property which the rest of the model must satisfy. We refer to [41] for a good account of composition and decomposition and other features which one would wish specifications to have. It is thus desirable to be able to translate specifications from the logical realm into behavioural formalisms, and *vice versa* from behavioural formalisms to logic-based specifications.

Our Contribution

Firstly, we show that Hennessy-Milner logic with greatest fixed points (the modal ν -calculus) and DMTS (with several initial states) are equally expressive, and we provide translations between these formalisms. The translations preserve structural properties of the formulae/systems and enable us to freely combine the two formalisms. In order to do so, we introduce an auxiliary intermediate formalism NAA (a nondeterministic extension of acceptance automata [33, 52]) and a related hybrid modal logic [13, 49], so that both turn out to be equivalent in expressiveness to the modal ν -calculus and DMTS. The established connection also allows for a graphical representation of ν -calculus formulae as DMTS. This extends the graphical representability of Hennessy-Milner logic (without fixed points) as modal transition systems [15, 40].

Example 1. Figures 3 and 4 show examples of important basic properties expressed both as formulae in the modal ν -calculus and as DMTS. We refer to Section 2 for the formal definitions. Note that the DMTS in Fig. 4 has two initial states; we will show in Section 3.5 that allowing multiple initial states is essential for the correspondence between DMTS and the modal ν -calculus.

Secondly, we show that there are natural operations of conjunction and disjunction for DMTS that mimic the ones of ν -calculus. As we work with multiple initial states, disjunction is readily defined, and conjunction extends the one for DMTS with a single initial state [7].

Thirdly, we introduce compositionality into the formalisms. For simplicity we assume CSP-style synchronisation of labels, but the construction can easily be generalised to other types of label synchronisation. We define a composition

operator for specifications which extends and soundly captures parallel composition of implementations, and we provide a solution to the open problem of the general quotient, see below.

The intuition of quotient, or decomposition, is as follows. Given a specification S of a final system to be constructed and T either an already implemented component or a specification of a service to be used, the task is to construct the most general specification of the rest of the system to be implemented, in such a way that when composed with any implementation of T, it conforms with the specification S. This specification is exactly the quotient S/T. We extend the quotient constructions for deterministic modal transition systems (MTS) and acceptance automata [52] to define the quotient for the full class of (possibly nondeterministic) DMTS. We also provide a more efficient procedure for (possibly nondeterministic) MTS. These constructions are the technically most demanding parts of the paper.

With the operations of composition and quotient, all four discussed formalisms form commutative residuated lattices [32, 58] (up to equivalence). This makes a rich algebraic theory available for compositional reasoning about specifications. Moreover, they form complete specification theories in the sense of [4]. Hence they support full compositionality and decomposition in the sense of [41]. Using our translations, we can transport these notions to the modal ν -calculus, thus also turning the modal ν -calculus into a complete specification theory.

Outline of the Paper

Section 2 introduces the formalisms of DMTS and the modal ν -calculus and the auxiliary formalisms of NAA and a new hybrid modal logic, whose formulae can serve as compact representations for NAA and is of interest in itself. In Section 3 the equivalence of these formalisms is discussed. In Section 4, we use our translations to turn the formalisms into complete specification theories. Section 5 discusses related work and Section 6 concludes.

2. Specification Formalisms

In this section we introduce the four specification formalisms with which this paper is concerned. For the rest of the paper, we fix a finite alphabet Σ . In each of the formalisms, the semantics of a specification is a set of implementations, in our case always a set of (finite) labelled transition systems (LTS) over Σ i.e. structures $\mathcal{I} = (S, s^0, \longrightarrow)$ consisting of a finite set S of states, an initial state $s^0 \in S$, and a transition relation $\longrightarrow \subseteq S \times \Sigma \times S$.

2.1. Disjunctive Modal Transition Systems

As customary, we write $s \xrightarrow{a} t$ instead of $(s, a, t) \in \dashrightarrow$, $s \longrightarrow N$ instead of $(s, N) \in \longrightarrow$, $s \xrightarrow{a} t$ if there exists t for which $s \xrightarrow{a} t$, and $s \not\sim t$ if there does not.

The intuition is that may-transitions $s \stackrel{a}{-} t$ specify which transitions are permitted in an implementation, whereas a must-transition $s \longrightarrow N$ stipulates a disjunctive requirement: at least one of the choices $(a,t) \in N$ has to be implemented. A DMTS $(S, S^0, - \rightarrow, \longrightarrow)$ is an *implementation* if $S^0 = \{s^0\}$ is a singleton and $\longrightarrow = \{(s, \{(a,t)\}) \mid s \stackrel{a}{-} t\}$.

DMTS were introduced in [44] in the context of equation solving. They are a natural extension of modal transition systems (MTS) [40]. We say that a DMTS $(S, S^0, \dashrightarrow, \longrightarrow)$ is a MTS if $S^0 = \{s^0\}$ is a singleton and for all $s \longrightarrow N$ it holds that $N = \{(a, t)\}$ is also a singleton. When speaking about MTS, we usually write $s \xrightarrow{a} t$ instead of $s \longrightarrow \{(a, t)\}$.

An LTS $(S, s^0, \longrightarrow)$ can be translated to a DMTS implementation $(S, S^0, \dashrightarrow, \longrightarrow)$ by setting $S^0 = \{s^0\}, \dashrightarrow \longrightarrow \longrightarrow$ and $\longrightarrow' = \{(s, \{(a, t)\}) \mid s \xrightarrow{a} t\}$. This defines an embedding of LTS into DMTS whose image are precisely the DMTS implementations.

Definition 2. Let $\mathcal{D}_1 = (S_1, S_1^0, -- \downarrow_1, \longrightarrow_1)$ and $\mathcal{D}_2 = (S_2, S_2^0, -- \downarrow_2, \longrightarrow_2)$ be DMTS. A relation $R \subseteq S_1 \times S_2$ is a *modal refinement* if for all $(s_1, s_2) \in R$ the following conditions hold:

- for all $s_1 \stackrel{a}{\dashrightarrow} t_1$ there is $t_2 \in S_2$ with $s_2 \stackrel{a}{\dashrightarrow} t_2$ and $(t_1, t_2) \in R$, and
- for all $s_2 \longrightarrow_2 N_2$ there is $s_1 \longrightarrow_1 N_1$ such that for each $(a, t_1) \in N_1$ there is $(a, t_2) \in N_2$ with $(t_1, t_2) \in R$.

We say that \mathcal{D}_1 modally refines \mathcal{D}_2 , denoted $\mathcal{D}_1 \leq_{\mathsf{m}} \mathcal{D}_2$, whenever there exists a modal refinement R such that for all $s_1^0 \in S_1^0$, there exists $s_2^0 \in S_2^0$ for which $(s_1^0, s_2^0) \in R$.

We write $\mathcal{D}_1 \equiv_{\mathsf{m}} \mathcal{D}_2$ if $\mathcal{D}_1 \leq_{\mathsf{m}} \mathcal{D}_2$ and $\mathcal{D}_2 \leq_{\mathsf{m}} \mathcal{D}_1$. For states $s_1 \in S_1$, $s_2 \in S_2$, we write $s_1 \leq_{\mathsf{m}} s_2$ if $(S_1, \{s_1\}, -\rightarrow_1, \longrightarrow_1) \leq_{\mathsf{m}} (S_2, \{s_2\}, -\rightarrow_2, \longrightarrow_2)$. Sometimes we will refer to the last property of a modal refinement relation, $\forall s_1^0 \in S_1^0 : \exists s_2^0 \in S_2^0 : (s_1^0, s_2^0) \in R$, as being *initialised*. Note that modal refinement is reflexive and transitive, *i.e.* a preorder on DMTS.

The set of implementations of a DMTS \mathcal{D} is $\llbracket \mathcal{D} \rrbracket = \{\mathcal{I} \leq_m \mathcal{D} \mid \mathcal{I} \text{ implementation}\}$. This is, thus, the set of all LTS which satisfy the specification given by the DMTS \mathcal{D} . We say that \mathcal{D}_1 thoroughly refines \mathcal{D}_2 , and write $\mathcal{D}_1 \leq_t \mathcal{D}_2$, if $\llbracket \mathcal{D}_1 \rrbracket \subseteq \llbracket \mathcal{D}_2 \rrbracket$. We write $\mathcal{D}_1 \equiv_t \mathcal{D}_2$ if $\mathcal{D}_1 \leq_t \mathcal{D}_2$ and $\mathcal{D}_2 \leq_t \mathcal{D}_1$. For states $s_1 \in S_1$, $s_2 \in S_2$, we write $\llbracket s_1 \rrbracket = \llbracket (S_1, \{s_1\}, -\rightarrow_1, -\rightarrow_1) \rrbracket$ and $s_1 \leq_t s_2$ if $\llbracket s_1 \rrbracket \subseteq \llbracket s_2 \rrbracket$.

The proposition below, which follows directly from transitivity of modal refinement, shows that modal refinement is *sound* with respect to thorough refinement; in the context of specification theories, this is what one would expect, and we only include it for completeness of presentation. It can be shown that modal refinement is also *complete* for *deterministic* DMTS [7], but we will not need this here.

Proposition 3. For all DMTS
$$\mathcal{D}_1$$
, \mathcal{D}_2 , $\mathcal{D}_1 \leq_{\mathsf{m}} \mathcal{D}_2$ implies $\mathcal{D}_1 \leq_{\mathsf{t}} \mathcal{D}_2$.

2.2. The Modal ν -Calculus

We recall the syntax and semantics of the modal ν -calculus, the fragment of the modal μ -calculus [36, 56] with only greatest fixed points. Instead of an

explicit greatest fixed point operator, we use the representation by equation systems in Hennessy-Milner logic developed in [42].

For a finite set X of variables, let $\mathcal{H}(X)$ be the set of *Hennessy-Milner formulae*, generated by the abstract syntax

$$\mathcal{H}(X) \ni \phi ::= \mathbf{tt} \mid \mathbf{ff} \mid x \mid \langle a \rangle \phi \mid [a] \phi \mid \phi \land \phi \mid \phi \lor \phi$$

for $a \in \Sigma$ and $x \in X$.

A declaration is a mapping $\Delta: X \to \mathcal{H}(X)$; we recall the greatest fixed point semantics of declarations from [42]. For an LTS $(S, s^0, \longrightarrow)$, an assignment is a mapping $\sigma: X \to 2^S$. The set of assignments forms a complete lattice with order $\sigma_1 \sqsubseteq \sigma_2$ iff $\sigma_1(x) \subseteq \sigma_2(x)$ for all $x \in X$ and least upper bound $(\bigcup_{i \in I} \sigma_i)(x) = \bigcup_{i \in I} \sigma_i(x)$.

The semantics of a formula is a subset of S, given relative to an assignment σ , defined as follows: $\{\mathbf{tt}\} \sigma = S$, $\{\mathbf{ff}\} \sigma = \emptyset$, $\{x\} \sigma = \sigma(x)$, $\{\phi \land \psi\} \sigma = \{\phi\} \sigma \cap \{\psi\} \sigma$, $\{\phi \lor \psi\} \sigma = \{\phi\} \sigma \cup \{\psi\} \sigma$, and

$$(\langle a \rangle \phi) \sigma = \{ s \in S \mid \exists s \xrightarrow{a} s' : s' \in (\phi) \sigma \},$$
$$([a]\phi) \sigma = \{ s \in S \mid \forall s \xrightarrow{a} s' : s' \in (\phi) \sigma \}.$$

The semantics of a declaration Δ is then the assignment defined by

$$(\!\![\Delta]\!\!] = \big| \quad \big| \big\{ \sigma: X \to 2^S \mid \forall x \in X: \sigma(x) \subseteq (\!\![\Delta(x)]\!\!] \sigma \big\};$$

the greatest (post) fixed point of Δ .

A ν -calculus expression is a structure $\mathcal{N}=(X,X^0,\Delta)$, with $X^0\subseteq X$ sets of variables and $\Delta:X\to\mathcal{H}(X)$ a declaration. We say that an LTS $\mathcal{I}=(S,s^0,\longrightarrow)$ implements (or models) the expression, and write $\mathcal{I}\models\mathcal{N}$, if there is $x^0\in X^0$ such that $s^0\in \mathbb{I}$ (\mathbb{I}). We write \mathbb{I} for the set of implementations (models) of a ν -calculus expression \mathcal{N} . As for DMTS, we write \mathbb{I} \mathbb{I} = \mathbb{I} (X, X, X) for X for DMTS, we write \mathbb{I} and thorough refinement of expressions and variables is defined accordingly.

We are now going to introduce a normal form for ν -calculus expressions. The purpose of this normal form is twofold. One is to allow us to define modal refinement for ν -calculus, an analogue to the DMTS modal refinement that can be seen as a sound approximation of the logical implication, cf. Proposition 3. The second purpose is to facilitate a simple translation between DMTS and ν -calculus expressions, see Section 3.1 below.⁴

Lemma 4. For any ν -calculus expression $\mathcal{N}_1 = (X_1, X_1^0, \Delta_1)$, there exists another expression $\mathcal{N}_2 = (X_2, X_2^0, \Delta_2)$ with $[\![\mathcal{N}_1]\!] = [\![\mathcal{N}_2]\!]$ and such that for any $x \in X$, $\Delta_2(x)$ is of the form

$$\Delta_2(x) = \bigwedge_{i \in I} \left(\bigvee_{j \in I_i} \langle a_{ij} \rangle x_{ij} \right) \wedge \bigwedge_{a \in \Sigma} [a] \left(\bigvee_{j \in I_a} y_{a,j} \right) \tag{1}$$

³Any ν -calculus expression is thoroughly equivalent to one with precisely one initial state, *i.e.* X^0 a singleton, however this is not true for ν -calculus expressions in normal form as defined below. See also Section 3.5.

⁴Note that this normal form is different from the one introduced in [8]. The original normal form did not allow for modal refinement and was less apt for the ν -calculus to DMTS translation.

for finite (possibly empty) index sets I, J_i , J_a , for $i \in I$ and $a \in \Sigma$, and all $x_{ij}, y_{a,j} \in X_2$. Additionally, for all $i \in I$ and $j \in J_i$, there exists $j' \in J_{a_{ij}}$ for which $x_{ij} \leq_t y_{a_{ij},j'}$. Also if at least one of the $J_i = \emptyset$ then $J_a = \emptyset$ for all a.

Remark that this normal form includes a semantic check $(x_{ij} \leq_t y_{a_{ij},j'})$, so it is not entirely syntactic.

PROOF. It is shown in [15] that any Hennessy-Milner formula is equivalent to one in so-called strong normal form, i.e. of the form $\bigvee_{i \in I} (\bigwedge_{j \in J_i} \langle a_{ij} \rangle \phi_{ij} \wedge \bigwedge_{a \in \Sigma} [a] \psi_{i,a})$ for HML formulas ϕ_{ij} , $\psi_{i,a}$ which are also in strong normal form, and such that for all $i, j, \phi_{ij} \leq_t \psi_{i,a_{ij}}$.

We can replace the ϕ_{ij} , $\psi_{i,a}$ by (new) variables x_{ij} , $y_{i,a}$ and add declarations $\Delta_2(x_{ij}) = \phi_{ij}$, $\Delta_2(y_{i,a}) = \psi_{i,a}$ to arrive at an expression in which all formulae are of the form $\Delta_2(x) = \bigvee_{i \in I} (\bigwedge_{j \in J_i} \langle a_{ij} \rangle x_{ij} \wedge \bigwedge_{a \in \Sigma} [a] y_{i,a})$ and such that for all $i, j, x_{ij} \leq_t y_{i,a_{ij}}$.

Now for each such formula, replace (recursively) x by new variables $\{\tilde{x}^i \mid i \in I\}$, similarly for y, and set $\Delta_2(\tilde{x}^i) = \bigwedge_{j \in J_i} \langle a_{ij} \rangle \big(\bigvee_k \tilde{x}^k_{ij} \big) \wedge \bigwedge_{a \in \Sigma} [a] \big(\bigvee_k \tilde{y}^k_{i,a} \big)$. Using initial variables $X_2^0 = \{\tilde{x}^i \mid x \in X_1^0\}$, the so-constructed ν -calculus expression is equivalent to the original one. We know that for all $i, j, \bigvee_k \tilde{x}^k_{ij} \leq_{\mathsf{t}} \bigvee_k \tilde{y}^k_{i,a_{ij}}$, hence for all i, j, k there exists k' such that $\tilde{x}^k_{ij} \leq_{\mathsf{t}} \tilde{y}^{k'}_{i,a_{ij}}$. We can thus rename variables and apply the distributivity of $\langle \cdot \rangle$ over \bigvee .

Finally, if at least one of the $J_i = \emptyset$ then Δ_2 is false and we can simply set $J_a = \emptyset$ for all a without changing the semantics of Δ_2 .

As this is a type of *conjunctive normal form*, it is clear that translating a ν -calculus expression into normal form may incur an exponential blow-up.

We introduce some notation for ν -calculus expressions in normal form which will make our life easier later. Let $\mathcal{N}=(X,X^0,\Delta)$ be such an expression and $x\in X$, with $\Delta(x)=\bigwedge_{i\in I}\left(\bigvee_{j\in J_i}\langle a_{ij}\rangle x_{ij}\right)\wedge\bigwedge_{a\in\Sigma}[a]\left(\bigvee_{j\in J_a}y_{a,j}\right)$ as in the lemma. Define $\Diamond(x)=\{\{(a_{ij},x_{ij})\mid j\in J_i\}\mid i\in I\}$ and, for each $a\in\Sigma$, $\square^a(x)=\{y_{a,j}\mid j\in J_a\}$. Note that now,

$$\Delta(x) = \bigwedge_{N \in \Diamond(x)} \Big(\bigvee_{(a,y) \in N} \langle a \rangle y\Big) \wedge \bigwedge_{a \in \Sigma} [a] \Big(\bigvee_{y \in \square^a(x)} y\Big) \,.$$

Definition 5. Let $\mathcal{N}_1 = (X_1, X_1^0, \Delta_1)$, $\mathcal{N}_2 = (X_2, X_2^0, \Delta_2)$ be ν -calculus expressions in normal form and $R \subseteq X_1 \times X_2$. The relation R is a modal refinement if it holds for all $(x_1, x_2) \in R$ that

- for all $a \in \Sigma$ and every $y_1 \in \square_1^a(x_1)$, there is $y_2 \in \square_2^a(x_2)$ for which $(y_1, y_2) \in R$, and
- for all $N_2 \in \Diamond_2(x_2)$ there is $N_1 \in \Diamond_1(x_1)$ such that for each $(a, y_1) \in N_1$, there exists $(a, y_2) \in N_2$ with $(y_1, y_2) \in R$.

We say that \mathcal{N}_1 modally refines \mathcal{N}_2 , denoted $\mathcal{N}_1 \leq_{\mathsf{m}} \mathcal{N}_2$, whenever there exists a modal refinement R such that for every $x_1^0 \in X_1^0$ there exists $x_2^0 \in X_2^0$ for which $(x_1^0, x_2^0) \in R$.

We say that a ν -calculus expression (X,X^0,Δ) in normal form is an imple-mentation if $X^0=\{x^0\}$ is a singleton, $\Diamond(x)=\{\{(a,y)\}\mid y\in\Box^a(x),a\in\Sigma\}$ and $\Box^a(x)=\emptyset$ for all $a\notin\Sigma$, for all $x\in X$.

We can translate an LTS $(S, s^0, \longrightarrow)$ to a ν -calculus expression (S, S^0, Δ) in normal form by setting $S^0 = \{s^0\}$ and $\Diamond(s) = \{\{(a,t)\} \mid s \stackrel{a}{\longrightarrow} t\}$ and $\Box^a(s) = \{t \mid s \stackrel{a}{\longrightarrow} t\}$ for all $s \in S$, $a \in \Sigma$. Like for DMTS, this defines an embedding of LTS into the modal ν -calculus whose image are precisely the ν -calculus implementations.

We will show below in Theorem 10 that for any LTS \mathcal{I} and any ν -calculus expression \mathcal{N} in normal form, $\mathcal{I} \models \mathcal{N}$ iff $\mathcal{I} \leq_m \mathcal{N}$, hence the fixed-point semantics of [42] and our refinement semantics agree. As a corollary of this result, we get that modal refinement is a sound approximation to logical implication, *i.e.* that $\mathcal{N}_1 \leq_m \mathcal{N}_2$ implies that for all implementations \mathcal{I} , $(\mathcal{I} \models \mathcal{N}_1) \Rightarrow (\mathcal{I} \models \mathcal{N}_2)$.

2.3. Nondeterministic Acceptance Automata

Definition 6. A nondeterministic acceptance automaton (NAA) is a structure $\mathcal{A} = (S, S^0, \text{Tran})$, with $S \supseteq S^0$ finite sets of states and initial states and Tran : $S \to 2^{2^{\Sigma \times S}}$ an assignment of transition constraints.

Acceptance automata were first introduced in [51] (see also [52], where a slightly different language-based approach is taken), based on the notion of acceptance trees in [33]; however, these are *deterministic*. We extend the formalism to a nondeterministic setting here. The following notion of modal refinement was introduced in [9].

Definition 7. Let $\mathcal{A}_1 = (S_1, S_1^0, \operatorname{Tran}_1)$ and $\mathcal{A}_2 = (S_2, S_2^0, \operatorname{Tran}_2)$ be NAA. A relation $R \subseteq S_1 \times S_2$ is a *modal refinement* if it holds for all $(s_1, s_2) \in R$ and all $M_1 \in \operatorname{Tran}_1(s_1)$ that there exists $M_2 \in \operatorname{Tran}_2(s_2)$ such that

$$\forall (a, t_1) \in M_1 : \exists (a, t_2) \in M_2 : (t_1, t_2) \in R,
\forall (a, t_2) \in M_2 : \exists (a, t_1) \in M_1 : (t_1, t_2) \in R.$$
(2)

We say that \mathcal{A}_1 modally refines \mathcal{A}_2 , and write $\mathcal{A}_1 \leq_{\mathsf{m}} \mathcal{A}_2$, whenever there exists a modal refinement R such that for all $s_1^0 \in S_1^0$, there exists $s_2^0 \in S_2^0$ for which $(s_1^0, s_2^0) \in R$.

An NAA is an *implementation* if $S^0 = \{s^0\}$ is a singleton and, for all $s \in S$, $\operatorname{Tran}(s) = \{M\}$ is a singleton. An LTS $(S, s^0, \longrightarrow)$ can be translated to an NAA by setting $S^0 = \{s^0\}$ and $\operatorname{Tran}(s) = \{\{(a,t) \mid s \stackrel{a}{\longrightarrow} t\}\}$. This defines an embedding of LTS into NAA whose image are precisely the NAA implementations. As for DMTS, we write $[\![\mathcal{A}]\!]$ for the set of implementations of an NAA \mathcal{A} , and through refinement and equivalence are defined accordingly.

2.4. Hybrid Modal Logic

As our fourth specification formalism, we introduce a hybrid modal logic, closely related to the Boolean modal transition systems of [9] and hybrid in the sense of [13, 49]: it contains nominals, and the semantics of a nominal is given as all sets which contain the nominal.

For a finite set X of nominals, let $\mathcal{L}(X)$ be the set of formulae generated by the abstract syntax $\mathcal{L}(X) \ni \phi \coloneqq \operatorname{tt} \mid \operatorname{ff} \mid \langle a \rangle x \mid \neg \phi \mid \phi \wedge \phi$, for $a \in \Sigma$ and $x \in X$. The semantics of a formula is a set of subsets of $\Sigma \times X$, given as follows: $(\operatorname{tt}) = 2^{\Sigma \times X}$, $(\operatorname{ff}) = \emptyset$, $(\neg \phi) = 2^{\Sigma \times X} \setminus (\phi)$, $(\langle a \rangle x) = \{M \subseteq \Sigma \times X \mid (a, x) \in M\}$, and $(\phi \wedge \psi) = (\phi) \cap (\psi)$. We also define disjunction $\phi_1 \vee \phi_2 = \neg (\neg \phi_1 \wedge \neg \phi_2)$.

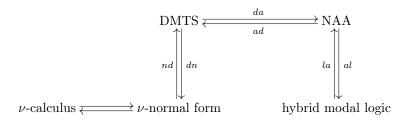

Figure 5: Six translations between specification formalisms

An \mathcal{L} -expression is a structure $\mathcal{E}=(X,X^0,\Phi)$ consisting of finite sets $X^0\subseteq X$ of variables and a mapping $\Phi:X\to\mathcal{L}(X)$. Such an expression is an implementation if $(\!\!\{\Phi(x)\!\!\})=\{M\}$ is a singleton for each $x\in X$.

Definition 8. Let $\mathcal{E}_1 = (X_1, X_1^0, \Phi_1)$ and $\mathcal{E}_2 = (X_2, X_2^0, \Phi_2)$ be \mathcal{L} -expressions. A relation $R \subseteq X_1 \times X_2$ is a *modal refinement* if it holds for all $(x_1, x_2) \in R$ and all $M_1 \in (\Phi_1(x_1))$ that there exists $M_2 \in (\Phi_2(x_2))$ such that

- $\forall (a, y_1) \in M_1 : \exists (a, y_2) \in M_2 : (y_1, y_2) \in R$,
- $\forall (a, y_2) \in M_2 : \exists (a, y_1) \in M_1 : (y_1, y_2) \in R.$

We say that \mathcal{E}_1 modally refines \mathcal{E}_2 , denoted $\mathcal{E}_1 \leq_{\mathsf{m}} \mathcal{E}_2$, whenever there exists a modal refinement R such that for all $x_1^0 \in X_1^0$, there exists $x_2^0 \in X_2^0$ for which $(x_1^0, x_2^0) \in R$.

We can translate an LTS $(S, s^0, \longrightarrow)$ to an \mathcal{L} -expression (S, S^0, Φ) by setting $S^0 = \{s^0\}$ and $\Phi(s) = \bigwedge_{s \stackrel{a}{\longrightarrow} t} \langle a \rangle t \wedge \bigwedge_{s \not\stackrel{b}{\longrightarrow} u} \neg \langle b \rangle u$. This defines an embedding of LTS into \mathcal{L} -expressions whose image are precisely the \mathcal{L} -implementations. As for DMTS, we write $[\![\mathcal{E}]\!]$ for the set of implementations of an \mathcal{L} -expression \mathcal{E} , and through refinement and equivalence are defined accordingly.

Remark 1. As all our four specification formalisms have the same type of implementations, labelled transition systems, we can use thorough refinement and equivalence cross-formalism. As an example example, for a given DMTS \mathcal{D} and an NAA \mathcal{A} , the expression $\mathcal{D} \leq_t \mathcal{A}$ is valid. We will use these types of thorough refinement and equivalence in many places throughout the paper.

3. Structural Equivalence

We proceed to show that our four specification formalisms are structurally equivalent. To this end, we shall expose six translations between them, see Fig. 5. Section 3.1 is concerned with dn and nd, Section 3.2 with al and la, and Section 3.3 with da and ad. We show in Theorems 9, 11 and 12 that all six translations preserve and reflect modal refinement.

3.1. DMTS vs. the Modal ν -Calculus

Our first two translations are rather straight-forward. For a DMTS $\mathcal{D} = (S, S^0, \dashrightarrow, \longrightarrow)$ and all $s \in S$, define $\Diamond(s) = \{N \mid s \longrightarrow N\}$ and, for each $a \in \Sigma$, $\Box^a(s) = \{t \mid s \stackrel{a}{\dashrightarrow} t\}$. Then, let

$$\Delta(s) = \bigwedge_{N \in \Diamond(s)} \left(\bigvee_{(a,t) \in N} \langle a \rangle t \right) \wedge \bigwedge_{a \in \Sigma} [a] \left(\bigvee_{t \in \square^a(s)} t \right)$$
 (3)

$$\begin{split} X_1 &= \langle a \rangle Y & \wedge [a] \mathbf{tt} \wedge [b] \mathbf{ff} \\ X_2 &= [a] \mathbf{ff} \wedge [b] \mathbf{tt} \\ Y &= \langle b \rangle (X_1 \vee X_2) \wedge [a] \mathbf{ff} \wedge [b] \mathbf{tt} \end{split}$$

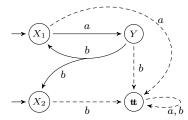

Figure 6: ν -calculus expression in normal form and its DMTS translation, cf. Example 2. The state corresponding to ff is inconsistent and not shown

and define the (normal-form) ν -calculus expression $dn(\mathcal{D}) = (S, S^0, \Delta)$.

Note how the formula precisely expresses that we demand at least one of every choice of disjunctive must-transitions (first part) and permit all may-transitions (second part); this is similar to the *characteristic formulae* of [40].

Conversely, for a ν -calculus expression $\mathcal{N} = (X, X^0, \Delta)$ in normal form, let

and define the DMTS $nd(\mathcal{N}) = (X, X^0, -\rightarrow, \longrightarrow)$. Note how this is a simple syntactic translation from diamonds to disjunctive must-transitions and from boxes to may-transitions. Also, the two translations are inverse to each other: $dn(nd(\mathcal{N})) = \mathcal{N} \text{ and } nd(dn(\mathcal{D})) = \mathcal{D}.$

Example 2. Consider the ν -calculus formula

$$X = (\langle a \rangle (\langle b \rangle X \wedge [a] \mathbf{ff}) \wedge [b] \mathbf{ff}) \vee [a] \mathbf{ff}.$$

Converting the formula into the normal form of Lemma 4 yields the result given in Fig. 6 (left), where both X_1 and X_2 are initial variables. The resulting DMTS is illustrated in Fig. 6 (right).

The following theorem follows easily:

Theorem 9. For all DMTS \mathcal{D}_1 , \mathcal{D}_2 , $\mathcal{D}_1 \leq_m \mathcal{D}_2$ iff $dn(\mathcal{D}_1) \leq_m dn(\mathcal{D}_2)$. For all ν -calculus expressions \mathcal{N}_1 , \mathcal{N}_2 in normal form, $\mathcal{N}_1 \leq_{\mathsf{m}} \mathcal{N}_2$ iff $nd(\mathcal{N}_1) \leq_{\mathsf{m}} nd(\mathcal{N}_2)$.

As a consequence, we can now show that the fixed-point semantics and our refinement semantics for the modal ν -calculus agree:

Theorem 10. For any LTS \mathcal{I} and any ν -calculus expression \mathcal{N} in normal form, $\mathcal{I} \models \mathcal{N} \text{ iff } \mathcal{I} \leq_m \mathcal{N}.$

PROOF. We show that $\mathcal{I} \leq_m \mathcal{D}$ iff $\mathcal{I} \models dn(\mathcal{D})$ for any DMTS \mathcal{D} ; the claim then follows because $\mathcal{I} \leq_{\mathsf{m}} \mathcal{N}$ iff $\mathcal{I} \leq_{\mathsf{m}} nd(\mathcal{N})$ iff $\mathcal{I} \models dn(nd(\mathcal{N})) = \mathcal{N}$. Write $\mathcal{I} = (I, i^0, \longrightarrow_I), \ \mathcal{D} = (S, S^0, \dashrightarrow, \longrightarrow), \ \text{and} \ dn(\mathcal{D}) = (S, S^0, \Delta).$

Write
$$\mathcal{I} = (I, i^0, \longrightarrow_I), \mathcal{D} = (S, S^0, \dashrightarrow, \longrightarrow), \text{ and } dn(\mathcal{D}) = (S, S^0, \Delta)$$

We start with the only-if part. The proof is done by coinduction. We define the assignment $\sigma: S \to 2^I$ as follows: $\sigma(t) = \{j \in I \mid j \leq_{\mathsf{m}} t\}$. We need to show that for every $s \in S$, $\sigma(s) \subseteq (\Delta(s)) \sigma$. Let $i \in \sigma(s)$.

As $i \leq_{\mathsf{m}} s$, we know that (1) $\forall s \longrightarrow N : \exists i \xrightarrow{a}_{I} j, (a, t) \in N : j \leq_{\mathsf{m}} t$ and (2) $\forall i \xrightarrow{a}_{I} j : \exists s \xrightarrow{a}_{t} t : j \leq_{\mathsf{m}} t$.

Due to (1), we see that for all $N \in \Diamond(s)$, there is $i \xrightarrow{a}_I j$ and $(a,t) \in N$ such that $j \in \sigma(t)$ and $i \in (\langle a \rangle t) \sigma$. Hence $i \in \bigwedge_{N \in \Diamond(s)} \bigvee_{(a,t) \in N} (\langle a \rangle t) \sigma = (\bigwedge_{N \in \Diamond(s)} \bigvee_{(a,t) \in N} \langle a \rangle t) \sigma$.

Due to (2), it holds that for every $a \in \Sigma$ and every $i \xrightarrow{a}_I j$, there is $t \in \Box^a(s)$ such that $j \in \sigma(t) \subseteq (\bigvee_{t \in \Box^a(s)} t) \sigma$. Hence $i \in \bigwedge_{a \in \Sigma} ([a](\bigvee_{t \in \Box^a(s)} t)) \sigma = (\bigwedge_{a \in \Sigma} [a](\bigvee_{t \in \Box^a(s)} t)) \sigma$. Altogether, we have shown that $i \in (\Delta(s)) \sigma$.

Clearly, there is $s^0 \in S^0$ such that $i^0 \in \sigma(s^0)$. Therefore, $\mathcal{I} \models dn(\mathcal{D})$.

For the other direction, define a relation $R \subseteq I \times S$ by $R = \{(j, t) \mid j \models t\}$. We show that R satisfies the conditions of modal refinement.

Let $(i, s) \in R$. As $i \models s$, we know that (1) $\forall N \in \Diamond(s) : \exists (a, t) \in N : i \models \langle a \rangle t$ and (2) $\forall a \in \Sigma : i \models [a](\bigvee_{t \in \square^a(s)} t)$.

By (1), we know that for all $s \longrightarrow N$, there is $(a,t) \in N$ and $i \xrightarrow{a}_I j$ such that $j \models t$. By (2), it holds that for all $i \xrightarrow{a}_I j$, there is $s \xrightarrow{a} t$ so that $j \models t$. We have shown that $i \leq_m s$.

Clearly, there is
$$s^0 \in S^0$$
 for which $(i^0, s^0) \in R$, hence $\mathcal{I} \leq_{\mathsf{m}} \mathcal{D}$.

3.2. NAA vs. Hybrid Modal Logic

Also the translations between NAA and our hybrid modal logic are straightforward. For an NAA $\mathcal{A}=(S,S^0,\mathrm{Tran})$ and all $s\in S$, let

$$\Phi(s) = \bigvee_{M \in \text{Tran}(s)} \left(\bigwedge_{(a,t) \in M} \langle a \rangle t \wedge \bigwedge_{(b,u) \notin M} \neg \langle b \rangle u \right)$$

and define the \mathcal{L} -expression $al(\mathcal{A}) = (S, S^0, \Phi)$.

For an \mathcal{L} -expression $\mathcal{E} = (X, X^0, \Phi)$ and all $x \in X$, let $Tran(x) = \langle\!\langle \Phi(x) \rangle\!\rangle$ and define the NAA $la(\mathcal{E}) = (X, X^0, Tran)$.

Theorem 11. For all NAA \mathcal{A}_1 , \mathcal{A}_2 , $\mathcal{A}_1 \leq_m \mathcal{A}_2$ iff $\mathit{al}(\mathcal{A}_1) \leq_m \mathit{al}(\mathcal{A}_2)$. For all \mathcal{L} -expressions \mathcal{E}_1 , \mathcal{E}_2 , $\mathcal{E}_1 \leq_m \mathcal{E}_2$ iff $\mathit{la}(\mathcal{E}_1) \leq_m \mathit{la}(\mathcal{E}_2)$.

PROOF. We show that for any NAA (S, S^0, Tran) and any \mathcal{L} -expression (S, S^0, Φ) , $\text{Tran}(s) = \langle\!\langle \Phi(s) \rangle\!\rangle$ for every $s \in S$, for both translations. For the second one, la, this is clear by definition, and for the first,

$$\begin{split} \langle\!\langle \Phi(s) \rangle\!\rangle &= \langle\!\langle \bigvee_{M \in \operatorname{Tran}(s)} \big(\bigwedge_{(a,t) \in M} \langle a \rangle t \wedge \bigwedge_{(b,u) \notin M} \neg \langle b \rangle u \big) \rangle \\ &= \bigcup_{M \in \operatorname{Tran}(s)} \big(\bigcap_{(a,t) \in M} \{M' \mid (a,t) \in M'\} \cap \bigcap_{(b,u) \notin M} \{M' \mid (b,u) \notin M'\} \big) \\ &= \bigcup_{M \in \operatorname{Tran}(s)} \big(\{M' \mid \forall (a,t) \in M : (a,t) \in M'\} \\ &= \bigcup_{M \in \operatorname{Tran}(s)} \big(\{M' \mid M \subseteq M'\} \cap \{M' \mid M' \subseteq M\} \big) \\ &= \bigcup_{M \in \operatorname{Tran}(s)} \{M\} = \operatorname{Tran}(s) \end{split}$$

as was to be shown.

3.3. DMTS vs. NAA

The translations between DMTS and NAA are somewhat more intricate. For a DMTS $\mathcal{D} = (S, S^0, -- \rightarrow, \longrightarrow)$ and all $s \in S$, let

$$\operatorname{Tran}(s) = \{ M \subseteq \Sigma \times S \mid \forall (a,t) \in M : s \xrightarrow{a} t, \forall s \longrightarrow N : N \cap M \neq \emptyset \}$$

and define the NAA $da(\mathcal{D}) = (S, S^0, \text{Tran})^5$

For an NAA $\mathcal{A}=(S,S^0,\operatorname{Tran})$, define the DMTS $ad(\mathcal{A})=(D,D^0,\dashrightarrow,\longrightarrow)$ as follows:

$$\begin{split} D &= \{M \in \operatorname{Tran}(s) \mid s \in S\} \cup \{ \not z \} \\ D^0 &= \{M^0 \in \operatorname{Tran}(s^0) \mid s^0 \in S^0\} \cup \{ \not z \mid \text{if } \exists s^0 \in S^0 : \operatorname{Tran}(s^0) = \emptyset \} \\ \longrightarrow &= \left\{ \left(M, \{(a, M') \mid M' \in \operatorname{Tran}(t)\}\right) \mid (a, t) \in M, \operatorname{Tran}(t) \neq \emptyset \right\} \cup \\ \left\{ \left(M, \{(a, \not z)\}\right) \mid (a, t) \in M, \operatorname{Tran}(t) = \emptyset \right\} \cup \left\{ \left(\not z, \emptyset\right) \right\} \\ - &\rightarrow &= \{(M, a, M') \mid \exists M \longrightarrow N : (a, M') \in N \} \end{split}$$

Note that the state spaces of \mathcal{A} and $ad(\mathcal{A})$ are not the same; the one of $ad(\mathcal{A})$ may be exponentially larger.

Theorem 12. For all DMTS \mathcal{D}_1 , \mathcal{D}_2 , $\mathcal{D}_1 \leq_m \mathcal{D}_2$ iff $da(\mathcal{D}_1) \leq_m da(\mathcal{D}_2)$. For all NAA \mathcal{A}_1 , \mathcal{A}_2 , $\mathcal{A}_1 \leq_m \mathcal{A}_2$ iff $ad(\mathcal{A}_1) \leq_m ad(\mathcal{A}_2)$.

PROOF. There are four parts to this proof, two implications to show the first claim of the theorem and two implications for the second claim.

• $\mathcal{D}_1 \leq_{\mathsf{m}} \mathcal{D}_2 \text{ implies } da(\mathcal{D}_1) \leq_{\mathsf{m}} da(\mathcal{D}_2)$:

Write $\mathcal{D}_1 = (S_1, S_1^0, -\rightarrow_1, \longrightarrow_1), \mathcal{D}_2 = (S_2, S_2^0, -\rightarrow_2, \longrightarrow_2)$. We have a modal refinement relation (in the DMTS sense) $R \subseteq S_1 \times S_2$. Now let $(s_1, s_2) \in R$ and $M_1 \in \text{Tran}_1(s_1)$, and define

$$M_2 = \{(a, t_2) \mid s_2 \xrightarrow{a}_{-} t_2, \exists (a, t_1) \in M_1 : (t_1, t_2) \in R\}.$$

We prove that $M_2 \in \operatorname{Tran}_2(s_2)$. First we notice that by construction, indeed $s_2 \xrightarrow{a}_2 t_2$ for all $(a, t_2) \in M_2$. Now let $s_2 \longrightarrow_2 N_2$; we need to show that $N_2 \cap M_2 \neq \emptyset$.

By DMTS refinement, we have $s_1 \longrightarrow_1 N_1$ such that $\forall (a, t_1) \in N_1 : \exists (a, t_2) \in N_2 : (t_1, t_2) \in R$. We know that $N_1 \cap M_1 \neq \emptyset$, so let $(a, t_1) \in N_1 \cap M_1$. Then there also is $(a, t_2) \in N_2$ with $(t_1, t_2) \in R$. But $(a, t_2) \in N_2$ implies $s_2 \stackrel{a}{\dashrightarrow} t_2$, hence $(a, t_2) \in M_2$.

Now the condition

$$\forall (a, t_2) \in M_2 : \exists (a, t_1) \in M_1 : (t_1, t_2) \in R$$

in the definition of NAA refinement is satisfied by construction. For the inverse condition, let $(a, t_1) \in M_1$, then $s_1 \xrightarrow{a}_{1} t_1$, so by DMTS refinement, there is $t_2 \in S_2$ with $s_2 \xrightarrow{a}_{2} t_2$ and $(t_1, t_2) \in R$, whence $(a, t_2) \in M_2$ by construction.

• $da(\mathcal{D}_1) \leq_{\mathsf{m}} da(\mathcal{D}_2) \text{ implies } \mathcal{D}_1 \leq_{\mathsf{m}} \mathcal{D}_2$:

⁵Note that there is an error in the corresponding formula in [8].

Let $R \subseteq S_1 \times S_2$ be a modal refinement relation in the NAA sense and $(s_1, s_2) \in R$. Let $s_1 \xrightarrow{a} t_1$ and $M_1 = \{(a, t_1)\} \cup \bigcup_{s_1 \longrightarrow_1 N_1} N_1$, then $M_1 \in \operatorname{Tran}_1(s_1)$ by construction. As R is a modal refinement, this implies that there is $M_2 \in \operatorname{Tran}_2(s_2)$ and $(a, t_2) \in M_2$ with $(t_1, t_2) \in R$, but then also $s_2 \xrightarrow{a} t_2$ as was to be shown.

Let $s_2 \longrightarrow_2 N_2$ and assume, for the sake of contradiction, that there is no $s_1 \longrightarrow_1 N_1$ for which $\forall (a,t_1) \in N_1 : \exists (a,t_2) \in N_2 : (t_1,t_2) \in R$ holds. Then for each $s_1 \longrightarrow_1 N_1$, there is an element $(a_{N_1},t_{N_1}) \in N_1$ for which there is no $(a_{N_1},t_2) \in N_2$ with $(t_{N_1},t_2) \in R$.

Let $M_1 = \{(a_{N_1}, t_{N_1}) \mid s_1 \longrightarrow_1 N_1\}$, then $M_1 \in \text{Tran}_1(s_1)$ by construction. Hence we have $M_2 \in \text{Tran}_2(s_2)$ satisfying the conditions in the definition of NAA refinement. By construction of $\text{Tran}_2(s_2)$, $s_2 \longrightarrow_2 N_2$ and $N_2 \cap M_2 \neq \emptyset$, so let $(a, t_2) \in N_2 \cap M_2$. Then there exists $(a, t_1) \in M_1$ for which $(t_1, t_2) \in R$, in contradiction to the definition of M_1 .

• $A_1 \leq_{\mathsf{m}} A_2 \text{ implies } ad(A_1) \leq_{\mathsf{m}} ad(A_2)$:

Write $\mathcal{A}_1 = (S_1, S_1^0, \operatorname{Tran}_1)$, $\mathcal{A}_2 = (S_2, S_2^0, \operatorname{Tran}_2)$, with DMTS translations $(D_1, D_1^0, \longrightarrow_1, -\rightarrow_1)$, $(D_2, D_2^0, \longrightarrow_2, -\rightarrow_2)$. We have a modal refinement relation (in the NAA sense) $R \subseteq S_1 \times S_2$. Define $R' \subseteq D_1 \times D_2$ by

```
R' = \{ (\not z, M_2) \mid M_2 \in D_2 \}
\cup \{ (M_1, M_2) \mid \exists (s_1, s_2) \in R : M_1 \in \operatorname{Tran}_1(s_1), M_2 \in \operatorname{Tran}(s_2),
\forall (a, t_1) \in M_1 : \exists (a, t_2) \in M_2 : (t_1, t_2) \in R,
\forall (a, t_2) \in M_2 : \exists (a, t_1) \in M_1 : (t_1, t_2) \in R \}.
```

We show that R' is a modal refinement in the DMTS sense. Let $(M_1, M_2) \in R'$. If $M_1 = \mbecaular$ then R' trivially satisfies the modal refinement conditions as there is no $\mbeta \xrightarrow{a}$ transition and every $M_2 \longrightarrow N_2$ is matched by $\mbeta \longrightarrow \emptyset$. Let us henceforth assume that $M_1 \neq \mbeta$.

Let $M_2 \longrightarrow_2 \{(a, \cancel{\xi})\}$. By construction of \longrightarrow_2 , there is $(a, t_2) \in M_2$ with $\operatorname{Tran}_2(t_2) = \emptyset$. Then $(M_1, M_2) \in R'$ implies that there must be $(a, t_1) \in M_1$ for which $(t_1, t_2) \in R$. As R is a NAA refinement, this means that $\operatorname{Tran}_1(t_1) = \emptyset$ and thus $M_1 \longrightarrow_1 \{(a, \cancel{\xi})\}$. Clearly, $(a, \cancel{\xi})$ is matched by $(a, \cancel{\xi})$ and $(\cancel{\xi}, \cancel{\xi}) \in R'$.

Let $M_2 \longrightarrow_2 N_2 \neq \{(a, \normalfoldsymbol{\not}{}_1\}$. By construction of \longrightarrow_2 , there is $(a, t_2) \in M_2$ such that $N_2 = \{(a, M_2') \mid M_2' \in \operatorname{Tran}_2(t_2)\} \neq \emptyset$. Then $(M_1, M_2) \in R'$ implies that there must be $(a, t_1) \in M_1$ for which $(t_1, t_2) \in R$.

If $\operatorname{Tran}_1(t_1) = \emptyset$, we know that $M_1 \longrightarrow_1 \{(a, \xi)\}$. We can then match (a, ξ) with arbitrary $(a, M_2') \in N_2$ as $(\xi, M_2') \in R'$.

If $\operatorname{Tran}_1(t_1) \neq \emptyset$, we can define $N_1 = \{(a, M_1') \mid M_1' \in \operatorname{Tran}_1(t_1)\}$, whence $M_1 \longrightarrow_1 N_1$. We show that $\forall (a, M_1') \in N_1 : \exists (a, M_2') \in N_2 : (M_1', M_2') \in R'$. Let $(a, M_1') \in N_1$, then $M_1' \in \operatorname{Tran}_1(t_1)$. From $(t_1, t_2) \in R$ we hence get $M_2' \in \operatorname{Tran}_2(t_2)$, and then $(a, M_2') \in N_2$ by construction of N_2 and $(M_1', M_2') \in R'$ due to the conditions of NAA refinement (applied to $(t_1, t_2) \in R$).

Let $M_1 \stackrel{a}{\dashrightarrow}_1 \not \xi$. We then have $M_1 \longrightarrow \{(a, \not \xi)\}$ which means that there is $(a, t_1) \in M_1$ with $\operatorname{Tran}_1(t_1) = \emptyset$. By $(M_1, M_2) \in R'$ we get $(a, t_2) \in M_2$, hence $M_2 \longrightarrow_2 N_2$ with some $(a, M_2') \in N_2$ and $M_2 \stackrel{a}{\dashrightarrow} M_2'$. By definition of R', $(\not \xi, M_2') \in R'$.

Let $M_1 \xrightarrow{a}_{1} M'_1 \neq \xi$, then we have $M_1 \longrightarrow_1 N_1$ for which $(a, M'_1) \in N_1$ and by construction of --₁. This in turn implies that there must be $(a, t_1) \in M_1$

such that $N_1 = \{(a, M_1'') \mid M_1'' \in \operatorname{Tran}_1(t_1)\} \neq \emptyset$, and then by $(M_1, M_2) \in R'$, we get $(a, t_2) \in M_2$ for which $(t_1, t_2) \in R$. Due to the conditions of NAA refinement, $\operatorname{Tran}_2(t_2) \neq \emptyset$. Let $N_2 = \{(a, M_2') \mid M_2' \in \operatorname{Tran}_2(t_2)\}$, then $M_2 \longrightarrow_2 N_2$ and hence $M_2 \xrightarrow{a} M_2'$ for all $(a, M_2') \in N_2$. Furthermore, the argument above shows that there is $(a, M_2') \in N_2$ for which $(M_1', M_2') \in R'$.

We miss to show that R' is initialised. If $\xi \in D_1^0$, then $(\xi, M_2^0) \in R'$ for any $M_2^0 \in D_2^0$. If $\xi \neq M_1^0 \in D_1^0$, then we have $s_1^0 \in S_1^0$ with $M_1^0 \in \operatorname{Tran}_1(s_1^0)$. As R is initialised, this entails that there is $s_2^0 \in S_2^0$ with $(s_1^0, s_2^0) \in R$, which gives us $M_2^0 \in \operatorname{Tran}_2(s_2^0)$ which satisfies the NAA refinement conditions, whence $(M_1^0, M_2^0) \in R'$.

• $ad(\mathcal{A}_1) \leq_{\mathsf{m}} ad(\mathcal{A}_2) \text{ implies } \mathcal{A}_1 \leq_{\mathsf{m}} \mathcal{A}_2$:

Let $R \subseteq D_1 \times D_2$ be a modal refinement relation in the DMTS sense and define $R' \subseteq S_1 \times S_2$ by

$$R' = \{(s_1, s_2) \mid \forall M_1 \in \text{Tran}_1(s_1) : \exists M_2 \in \text{Tran}_2(s_2) : (M_1, M_2) \in R\};$$

we will show that R' is an NAA modal refinement.

Observe first that $(M_1, \mbox{$\rlap/$}) \in R$ implies $M_1 = \mbox{$\rlap/$}$ as $\mbox{$\rlap/$}$ is the only state in D_1 that has a must transition $\longrightarrow_1 \emptyset$. We shall occasionally refer to this observation in the following.

Let $(s_1, s_2) \in R'$ and $M_1 \in \text{Tran}_1(s_1)$, then by construction of R', we have $M_2 \in \text{Tran}_2(s_2)$ with $(M_1, M_2) \in R$.

Let $(a, t_2) \in M_2$; we need to find $(a, t_1) \in M_1$ such that $(t_1, t_2) \in R'$.

If $\operatorname{Tran}_2(t_2) = \emptyset$, then $M_2 \longrightarrow_2 \{(a, \normalfooting)\}$. From $(M_1, M_2) \in R$ we get $M_1 \longrightarrow_1 N_1$ such that all $(a, M_1') \in N_1$ are matched by (a, \normalfooting) with $(M_1', \normalfooting) \in R$. By the observation above, this means that $M_1' = \normalfooting$ and thus $N_1 = \{(a, \normalfooting)\}$ due to the construction. This means that there exists $(a, t_1) \in M_1$ with $\operatorname{Tran}_1(t_1) = \emptyset$. Hence $(t_1, t_2) \in R'$.

If $\operatorname{Tran}_2(t_2) \neq \emptyset$, define $N_2 = \{(a, M_2') \mid M_2' \in \operatorname{Tran}_2(t_2)\}$, then $M_2 \longrightarrow_2 N_2$. Now $(M_1, M_2) \in R$ implies that there must be $M_1 \longrightarrow_1 N_1$ satisfying $\forall (a, M_1') \in N_1 : \exists (a, M_2') \in N_2 : (M_1', M_2') \in R$. If $N_1 = \{(a, \xi)\}$, we have $(a, t_1) \in M_1$ with $\operatorname{Tran}_1(t_1) = \emptyset$ and thus trivially $(t_1, t_2) \in R'$. Otherwise, we have $(a, t_1) \in M_1$ such that $N_1 = \{(a, M_1') \mid M_1' \in \operatorname{Tran}_1(t_1)\}$; we only miss to show that $(t_1, t_2) \in R'$.

Let $M_1' \in \operatorname{Tran}_1(t_1)$, then $(a, M_1') \in N_1$, hence there is $(a, M_2') \in N_2$ with $(M_1', M_2') \in R$, but $(a, M_2') \in N_2$ also entails $M_2' \in \operatorname{Tran}_2(t_2)$; thus $(t_1, t_2) \in R'$. Let now $(a, t_1) \in M_1$; we need to find $(a, t_2) \in M_2$ such that $(t_1, t_2) \in R'$.

If $\operatorname{Tran}_1(t_1) = \emptyset$, then $M_1 \longrightarrow_1 \{(a, \note left)\}$ and $M_1 \stackrel{a}{\dashrightarrow} \note left \ell$. By modal refinement, we have $M_2 \stackrel{a}{\dashrightarrow} M'_2$ with $(\note left \ell, M'_2) \in R$. In any case (whether $M'_2 = \note left \ell$ or not), this means that there exists some $(a, t_2) \in M_2$ and trivially $(t_1, t_2) \in R'$.

In case $\operatorname{Tran}_1(t_1) \neq \emptyset$, define $N_1 = \{(a, M_1') \mid M_1' \in \operatorname{Tran}_1(t_1)\}$, then $N_1 \neq \emptyset$ and $M_1 \longrightarrow_1 N_1$. Now let $(a, M_1') \in N_1$, then $M_1 \stackrel{a}{-} \to_1 M_1'$, hence we have $M_2 \stackrel{a}{-} \to_2 M_2'$ for some $(M_1', M_2') \in R$ by modal refinement. Note that $M_1' \neq \emptyset$ implies $M_2' \neq \emptyset$ due to the observation above. By construction of $-- \to_2$, this implies that there is $M_2 \longrightarrow_2 N_2$ with $(a, M_2') \in N_2$, and we have $(a, t_2) \in M_2$ for which $N_2 = \{(a, M_2'') \mid M_2'' \in \operatorname{Tran}_2(t_2)\}$. We show that $(t_1, t_2) \in R'$.

Let $M_1'' \in \operatorname{Tran}_1(t_1)$, then $(a, M_1'') \in N_1$, thus $M_1 \xrightarrow{a} M_1''$, so that there is $M_2 \xrightarrow{a} M_2''$ with $(M_1'', M_2'') \in R$. By construction of $-- \downarrow_2$, there is $M_2 \longrightarrow_2 N_2'$ with $(a, M_2'') \in N_2'$, hence also $M_2'' \in \operatorname{Tran}_2(t_2)$.

We miss to show that R' is initialised. Let $s_1^0 \in S_1^0$; if $\operatorname{Tran}_1(s_1^0) = \emptyset$, then trivially $(s_1^0, s_2^0) \in R'$ for any $s_2^0 \in S_2^0$. If $\operatorname{Tran}_1(s_1^0) \neq \emptyset$, then there is $M_1^0 \in \operatorname{Tran}_1(s_1^0)$. As R is initialised, this gets us $M_2^0 \in D_2$ with $(M_1^0, M_2^0) \in R$, but $M_2^0 \in \operatorname{Tran}_2(s_2^0)$ for some $s_2^0 \in S_2^0$, and then $(s_1^0, s_2^0) \in R'$.

Corollary 13. For all DMTS \mathcal{D} , ν -calculus expressions \mathcal{N} , NAA \mathcal{A} , and \mathcal{L} -expressions \mathcal{E} , $dn(\mathcal{D}) \equiv_t da(\mathcal{D}) \equiv_t \mathcal{D}$, $nd(\mathcal{N}) \equiv_t \mathcal{N}$, $ad(\mathcal{A}) \equiv_t al(\mathcal{A}) \equiv_t \mathcal{A}$, and $la(\mathcal{E}) \equiv_t \mathcal{E}$.

3.4. Translation Complexity

We have shown that our four specification formalisms are structurally equivalent, which will be useful for us from a theoretical point of view. From a practical point of view however, some of the translations may incur exponential blow-ups, hence care has to be taken. On the other hand, all our translations can be implemented in an on-the-fly manner, only creating states when necessary.

We already noticed that the translation of ν -calculus expressions into normal form may incur an exponential blow-up, so this also affects our translation from the modal ν -calculus to DMTS. When considering only normal-form expressions, the translations to and from DMTS incur no blow-ups.

When translating from NAA to our hybrid modal logic, we see that, due to the complementation $(b,u) \notin M$, the length of a formula $\Phi(s)$ is quadratic in the representation of $\operatorname{Tran}(s)$. For the reverse translation, the number of Tran constraints can be exponential in the number of states. The worst case is $\Phi(s) = \mathbf{tt}$, which gets translated to $\operatorname{Tran}(s) = 2^{2^{\Sigma \times S}}$.

Remark 2. There is a direct translation from DMTS to hybrid modal logic: for a DMTS $\mathcal{D} = (S, S^0, \dashrightarrow, \longrightarrow)$, define $dl(\mathcal{D}) = (S, S^0, \Phi)$ with

$$\Phi(s) = \bigwedge_{s \longrightarrow N} \bigvee_{(a,t) \in N} \langle a \rangle t \wedge \bigwedge_{s \nearrow \bullet u} \neg \langle a \rangle u$$

for all $s \in S$. This translation is again quadratic, and $da(\mathcal{D}) = la(dl(\mathcal{D}))$.

The translations between DMTS and NAA may involve exponential blow-ups both ways. For the first translation, we can see this by considering the one-state DMTS ($\{s\}, \{s\}, \dashrightarrow, \longrightarrow$) with $\dashrightarrow = \{(s, a, s) \mid a \in \Sigma\}$ and $\longrightarrow = \emptyset$. Then $\operatorname{Tran}(s) = 2^{2^{\Sigma \times S}}$.

The fact that also the translation from NAA to DMTS may be exponential in space is evident from the definition. To see that this blow-up is unavoidable, we expose a special property of the Tran-sets arising in the DMTS-to-NAA translation.

Lemma 14. Let $\mathcal{D} = (S, S^0, \dashrightarrow, \longrightarrow)$ be a DMTS and $s \in S$. For all $M_1, M_2 \in \operatorname{Tran}(s)$ and all $M \subseteq \Sigma \times S$ with $M_1 \subseteq M \subseteq M_1 \cup M_2$, also $M \in \operatorname{Tran}(s)$.

PROOF. For i = 1, 2, since $M_i \in \text{Tran}(s)$, we know that

- for all $(a,t) \in M_i$, $s \xrightarrow{a} t$, and
- for all $s \longrightarrow N$, there is $(a, t) \in M_i \cap N$.

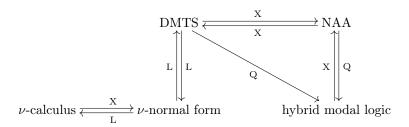

Figure 7: Complexity of the translations between specification formalisms. "L" stands for linear (no blow-up), "Q" for quadratic blow-up, and "X" for exponential blow-up

Now as $M \subseteq M_1 \cup M_2$, it directly follows that for all $(a, t) \in M$, we have $s \xrightarrow{a} t$. Moreover, since $M_1 \subseteq M$, we also have that for all $s \longrightarrow N$, there exists $(a, t) \in M \cap N$. As a consequence, $M \in \text{Tran}(s)$.

Using this, we can show the following.⁶

Lemma 15. There exists a one-state NAA \mathcal{A} for which any DMTS $\mathcal{D} \equiv_t \mathcal{A}$ has at least 2^{n-1} states, where n is the size of the alphabet Σ .

PROOF. Let $\Sigma = \{a_1, \ldots, a_n\}$ and $\mathcal{A} = (\{s^0\}, \{s^0\}, \text{Tran})$ the NAA with $\text{Tran}(s^0) = \{M \subseteq \Sigma \times \{s^0\} \mid \exists k : |M| = 2k\}$ the transition constraint containing all disjunctive choices of even cardinality. Let $\mathcal{D} = (T, T^0, \dashrightarrow, \longrightarrow)$ be a DMTS with $\mathcal{D} \equiv_{\mathsf{t}} \mathcal{A}$; we claim that \mathcal{D} must have at least 2^{n-1} initial states.

Assume, for the purpose of contradiction, that $T^0 = \{t_1^0, \ldots, t_m^0\}$ with $m < 2^{n-1}$. As $\mathcal{D} \equiv_{\mathsf{t}} \mathcal{A}$, we must have $\bigcup_{i=1}^m \operatorname{Tran}(t_i^0) = \{M \subseteq \Sigma \times T \mid \exists k : |M| = 2k\}$, so that there is an index $j \in \{1, \ldots, m\}$ for which $\operatorname{Tran}(t_j^0) = \{M_1, M_2\}$ contains two different disjunctive choices from $\operatorname{Tran}(s^0)$. By Lemma 14, also $M \in \operatorname{Tran}(t_j^0)$ for any M with $M_1 \subseteq M \subseteq M_1 \cup M_2$. But $M_1 \cup M_2$ has greater cardinality than M_1 , so that there will be an $M \in \operatorname{Tran}(t_j^0)$ with odd cardinality. \square

Figure 7 sums up the translation complexities.

3.5. Initial States

We finish this section with a justification for why we allow our specifications to have several (or possibly zero) initial states. The first lemma shows that for NAA, and up to *thorough* refinement, this is inessential; due to their close relationship, this also holds for \mathcal{L} -expressions.

Lemma 16. For any NAA A_1 , there is an NAA $A_2 = (S_2, S_2^0, \text{Tran}_2)$ with $S_2^0 = \{s_2^0\}$ a singleton and $A_1 \equiv_t A_2$.

PROOF. Write $\mathcal{A}_1=(S_1,S_1^0,\operatorname{Tran}_1)$. If $S_1^0=\emptyset$, we can let $S_2=S_2^0=\{s_2^0\}$ and $\operatorname{Tran}_2(s_2^0)=\emptyset$. Otherwise, we let $S_2=S_1\cup\{s_2^0\}$, where s_2^0 is a new state, and $\operatorname{Tran}_2(s)=\operatorname{Tran}_1(s)$ for $s\in S_1$, $\operatorname{Tran}_2(s_2^0)=\bigcup_{s_1^0\in S_1^0}\operatorname{Tran}_1(s_1^0)$. Let $R=\operatorname{id}_{S_1}\cup\{(s_1^0,s_2^0)\mid s_1^0\in S_1^0\}$, then R is easily seen to be a modal refinement showing $\mathcal{A}_1\leq_{\mathsf{m}}\mathcal{A}_2$.

⁶We wish to thank Ilya Bogdanov for discussions on this subject [45].

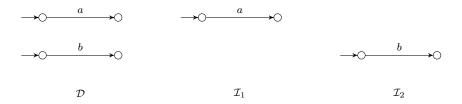

Figure 8: DMTS \mathcal{D} with two initial states and its two implementations \mathcal{I}_1 , \mathcal{I}_2

We show that $A_2 \leq_t A_1$. Let $\mathcal{I} = (S, s^0, \longrightarrow) \in [A_2]$, then we have a modal refinement $R_2 \subseteq S \times S_2$, *i.e.* such that for all $(s, s_2) \in R_2$, there exists $M_2 \in \text{Tran}_2(s_2)$ for which

$$\forall s \xrightarrow{a} t : \exists (a, t_2) \in M_2 : (t, t_2) \in R_2,$$

$$\forall (a, t_2) \in M_2 : \exists s \xrightarrow{a} t : (t, t_2) \in R_2.$$
 (4)

Now $(s^0, s_2^0) \in R_2$ implies that there must be $M_2 \in \text{Tran}_2(s_2^0)$ for which (4) holds, but by definition of $\text{Tran}_2(s_2^0)$, this entails that there is $s_1^0 \in S_1^0$ for which $M_2 \in \text{Tran}_1(s_1^0)$. Define $R_1 \subseteq S \times S_1$ by

$$R_1 = \{(s, s_2) \mid (s, s_2) \in R_2, s_2 \neq s_2^0\} \cup \{(s^0, s_1^0)\},\$$

then R_1 is a modal refinement showing $\mathcal{I} \leq_{\mathsf{m}} \mathcal{A}_1$.

In order to show that the above statement does not hold for DMTS, we expose a special property of DMTS with single initial states, cf. [10, Example 7.8]. Recall that for LTS $\mathcal{I}_1 = (S_1, s_1^0, \longrightarrow_1), \mathcal{I}_2 = (S_2, s_2^0, \longrightarrow_2)$, their nondeterministic sum is given by $\mathcal{I}_1 + \mathcal{I}_2 = (S, s^0, \longrightarrow)$ with $S = S_1 \cup S_2 \cup \{s^0\}$ (with the unions disjoint), where s^0 is a new state, and transitions $s \xrightarrow{a} t$ iff $s \xrightarrow{a}_1 t$ or $s \xrightarrow{a}_2 t$ together with $s^0 \xrightarrow{a} t$ for all t with $s_1^0 \xrightarrow{a}_1 t$ or $s_2^0 \xrightarrow{a}_2 t$.

Lemma 17. If $\mathcal{D} = (S, \{s^0\}, \dashrightarrow, \longrightarrow)$ is a DMTS with a single initial state and $\mathcal{I}_1, \mathcal{I}_2 \in [\![\mathcal{D}]\!]$, then also $\mathcal{I}_1 + \mathcal{I}_2 \in [\![\mathcal{D}]\!]$.

PROOF. Let i_1^0 and i_2^0 be the initial states of \mathcal{I}_1 and \mathcal{I}_2 , respectively. Let further i^0 be the initial state of $\mathcal{I}_1 + \mathcal{I}_2$. Assume that we have modal refinements R_1 and R_2 such that $(i_1^0, s^0) \in R_1$ and $(i_2^0, s^0) \in R_2$. Let $R = R_1 \cup R_2 \cup \{(i^0, s^0)\}$. Clearly, R is a modal refinement witnessing $\mathcal{I}_1 + \mathcal{I}_2 \leq_{\mathsf{m}} \mathcal{D}$.

Now let \mathcal{D} be the DMTS, with *two* initial states, depicted in Fig. 8, then $\llbracket \mathcal{D} \rrbracket = \{\mathcal{I}_1, \mathcal{I}_2\}$ as also seen in Fig. 8, but $\mathcal{I}_1 + \mathcal{I}_2 \notin \llbracket \mathcal{D} \rrbracket$. Hence \mathcal{D} is not thoroughly equivalent to any DMTS with a single initial state.

Applying the construction from the proof of Lemma 16 to the NAA generated by the DMTS in Fig. 8 gives an NAA $A_2 = (S_2, \{s_2^0\}, \text{Tran}_2)$ with $\text{Tran}_2(s_2^0) = \{\{(a, s_1)\}, \{(b, t_1)\}\}$ (where s_1 and t_1 are the target states of the a and b transitions in \mathcal{D} , respectively). This specifies an exclusive disjunction: one of a and b has to be implemented, but not both. This also serves to show that Lemma 17 does not hold for NAA.

Corollary 18. There is a DMTS
$$\mathcal{D}_1$$
 for which there is no DMTS $\mathcal{D}_2 = (S_2, S_2^0, -\rightarrow, \longrightarrow)$ with $S_2^0 = \{s_2^0\}$ a singleton and $\mathcal{D}_1 \equiv_{\mathfrak{t}} \mathcal{D}_2$.

Due to their close relationship with DMTS, this property also holds for ν -calculus expressions in normal form: there exist ν -calculus expressions which are not equivalent to any normal-form ν -calculus expression with a single initial variable. (Of course, omitting "normal form" would make this statement invalid; as disjunction is part of the syntax, any ν -calculus expression is thoroughly equivalent to one with only one initial variable.)

We also remark that the above argument can easily be extended to show that for any $k \in \mathbb{N}$, there exists a DMTS with k+1 initial states which is not thoroughly equivalent to any DMTS with at most k initial states.

Using again the example in Fig. 8, we can also show that the statement in Lemma 16 does *not* hold when thorough equivalence is replaced by modal equivalence. Let $\mathcal{A}_1 = da(\mathcal{D})$, with initial states s^0 and t^0 , be the NAA translation of the DMTS in Fig. 8 and assume that there exists an NAA \mathcal{A}_2 with single initial state s_2^0 for which $\mathcal{A}_2 \leq_{\mathsf{m}} \mathcal{A}_1$. Then there is a modal refinement R with $(s_2^0, s^0), (s_2^0, t^0) \in R$. Let $M_2 \in \mathrm{Tran}_2(s_2^0)$, then by $(s_2^0, s^0) \in R$, there must be some $(a, t_2) \in M_2$ with $(t_2, s_1) \in R$. By $(s_2^0, t^0) \in R$, this implies that there must be $(a, t_1) \in \mathrm{Tran}_1(t^0)$, a contradiction.

4. Specification Theory

Behavioural specifications typically come equipped with operations which allow for *compositional reasoning*, viz. conjunction, composition and quotient, cf. [4]. On deterministic MTS, these operations can be given easily using simple structural operational rules. For non-deterministic systems this is significantly harder.

We remark that composition and quotient operators are well-known from some logics, such as, e.g. linear [31] or spatial logic [19], and were extended to quite general contexts [20]. However, whereas these operators are part of the formal syntax in those logics, for us they are simply operations on logical expressions (or DMTS, or NAA). Consequently, composition is generally only a sound over-approximation of the semantic composition.

Given the structural equivalence of DMTS, the modal ν -calculus, NAA, and our hybrid modal logic exposed in the previous section, it suffices to introduce the operations for *one* of the four types of specifications. On the other hand, we will often state properties for *all* four types of specifications at the same time, letting \mathcal{S} stand for a specification of any type.

4.1. Disjunction and Conjunction

Disjunction of specifications is easily defined as we allow multiple initial states. For DMTS $\mathcal{D}_1 = (S_1, S_1^0, -\rightarrow_1, \longrightarrow_1)$, $\mathcal{D}_2 = (S_2, S_2^0, -\rightarrow_2, \longrightarrow_2)$, we can hence define $\mathcal{D}_1 \vee \mathcal{D}_2 = (S_1 \cup S_2, S_1^0 \cup S_2^0, -\rightarrow_1 \cup -\rightarrow_2, \longrightarrow_1 \cup \longrightarrow_2)$ (with all unions disjoint). Similar definitions are available for the other types of specifications, and disjunction commutes with the translations.

Conjunction for DMTS is an extension of the construction from [7] for multiple initial states. Given two DMTS $\mathcal{D}_1 = (S_1, S_1^0, -\rightarrow_1, \longrightarrow_1), \mathcal{D}_2 = (S_2, S_2^0, -\rightarrow_2, \longrightarrow_2)$, we define $\mathcal{D}_1 \wedge \mathcal{D}_2 = (S, S^0, -\rightarrow, \longrightarrow)$ with $S = S_1 \times S_2$, $S^0 = S_1^0 \times S_2^0$, and

•
$$(s_1, s_2) \xrightarrow{a} (t_1, t_2)$$
 iff $s_1 \xrightarrow{a}_1 t_1$ and $s_2 \xrightarrow{a}_2 t_2$,

- for all $s_1 \longrightarrow_1 N_1$, $(s_1, s_2) \longrightarrow \{(a, (t_1, t_2)) \mid (a, t_1) \in N_1, s_2 \stackrel{a}{\longrightarrow}_2 t_2\}$,
- for all $s_2 \longrightarrow_2 N_2$, $(s_1, s_2) \longrightarrow \{(a, (t_1, t_2)) \mid (a, t_2) \in N_2, s_1 \stackrel{a}{\dashrightarrow}_1 t_1\}$.

For NAA, conjunction can be defined using auxiliary projection functions $\pi_i: 2^{\Sigma \times S_1 \times S_2} \to 2^{\Sigma \times S_i}$ given by

$$\pi_1(M) = \{(a, s_1) \mid \exists s_2 \in S_2 : (a, s_1, s_2) \in M\},\$$

 $\pi_2(M) = \{(a, s_2) \mid \exists s_1 \in S_1 : (a, s_1, s_2) \in M\}.$

Then for NAA $A_1 = (S_1, S_1^0, \operatorname{Tran}_1), A_2 = (S_2, S_2^0, \operatorname{Tran}_2), \text{ we let } A_1 \wedge A_2 = (S, S^0, \operatorname{Tran}), \text{ with } S = S_1 \times S_2, S^0 = S_1^0 \times S_2^0 \text{ and } \operatorname{Tran}((s_1, s_2)) = \{M \subseteq \Sigma \times S \mid \pi_1(M) \in \operatorname{Tran}_1(s_1), \pi_2(M) \in \operatorname{Tran}_2(s_2)\}.$

We can also define conjunction for \mathcal{L} -expressions, using similar auxiliary mappings on formulae. For sets X_1 , X_2 and $i \in \{1, 2\}$, we define $\rho_i : \mathcal{L}(X_i) \to \mathcal{L}(X_1 \times X_2)$ inductively, by

- $\rho_i(\mathbf{tt}) = \mathbf{tt}$, $\rho_i(\mathbf{ff}) = \mathbf{ff}$, $\rho_i(\neg \phi) = \neg \rho_i(\phi)$, $\rho_i(\phi_i \land \phi_2) = \rho_i(\phi_i) \land \rho_i(\phi_2)$,
- $\rho_1(\langle a \rangle x_1) = \bigvee_{x_2 \in X_2} \langle a \rangle (x_1, x_2),$
- $\rho_2(\langle a \rangle x_2) = \bigvee_{x_1 \in X_1} \langle a \rangle (x_1, x_2).$

Then, for \mathcal{L} -expressions $\mathcal{E}_1 = (X_1, X_1^0, \Phi_1), \mathcal{E}_2 = (X_2, X_2^0, \Phi_2), \text{ we let } \mathcal{E}_1 \wedge \mathcal{E}_2 = (X_1 \times X_2, X_1^0 \times X_2^0, \Phi) \text{ with } \Phi((x_1, x_2)) = \rho_1(\Phi_1(x_1)) \wedge \rho_2(\Phi_2(x_2)).$

Lemma 19. For all DMTS \mathcal{D}_1 , \mathcal{D}_2 , NAA \mathcal{A}_1 , \mathcal{A}_2 , and \mathcal{L} -expressions \mathcal{E}_1 , \mathcal{E}_2 , $da(\mathcal{D}_1 \wedge \mathcal{D}_2) = da(\mathcal{D}_1) \wedge da(\mathcal{D}_2)$, $al(\mathcal{A}_1 \wedge \mathcal{A}_2) = al(\mathcal{A}_1) \wedge al(\mathcal{A}_2)$, and $la(\mathcal{E}_1 \wedge \mathcal{E}_2) = la(\mathcal{E}_1) \wedge la(\mathcal{E}_2)$.

Note that above makes no statement about the ad translation; due to the change of state space during the translation, equality does not hold here.

PROOF. The last two claims follow easily once one notices that for $i \in \{1, 2\}$ and all M, $M \models \rho_i(\phi)$ iff $\pi_i(M) \models \phi$. To show the first claim, let $\mathcal{D}_1 = (S_1, S_1^0, -\rightarrow_1, \longrightarrow_1)$ and $\mathcal{D}_2 = (S_2, S_2^0, -\rightarrow_2, \longrightarrow_2)$ be DMTS, with NAA translations $da(\mathcal{D}_1) = (S_1, S_1^0, \operatorname{Tran}_1)$ and $da(\mathcal{D}_2) = (S_2, S_2^0, \operatorname{Tran}_2)$. Write $\mathcal{A}^{\wedge} = da(\mathcal{D}_1 \wedge \mathcal{D}_2)$ and $\mathcal{A}_{\wedge} = da(\mathcal{D}_1) \wedge da(\mathcal{D}_2)$; we show that $\mathcal{A}^{\wedge} = \mathcal{A}_{\wedge}$.

First, remark that \mathcal{A}^{\wedge} and \mathcal{A}_{\wedge} have precisely the same state space $S_1 \times S_2$ and initial states $S_1^0 \times S_2^0$. We now show that they have the same transition constraints. Let $\operatorname{Tran}_{\wedge}$ (resp. $\operatorname{Tran}^{\wedge}$) be the transition constraints mapping of \mathcal{A}_{\wedge} (resp. \mathcal{A}^{\wedge}). Let $(s_1, s_2) \in S_1 \times S_2$ and $M \in \operatorname{Tran}_{\wedge}(s_1, s_2)$.

By construction of $\operatorname{Tran}_{\wedge}$, there must be $M_1 \in \operatorname{Tran}_1(s_1)$ and $M_2 \in \operatorname{Tran}_2(s_2)$ such that $\pi_1(M) = M_1$ and $\pi_2(M) = M_2$. We show that $M \in \operatorname{Tran}^{\wedge}(s_1, s_2)$. Let $(a, (t_1, t_2)) \in M$. Since $\pi_1(M) = M_1$ and $\pi_2(M) = M_2$, we have $(a, t_1) \in M_1$ and $(a, t_2) \in M_2$. As a consequence, there are transitions $s_1 \stackrel{a}{\dashrightarrow} t_1$ and $s_2 \stackrel{a}{\dashrightarrow} t_2$ in \mathcal{D}_1 and \mathcal{D}_2 , respectively. Thus, by construction, there is a transition $(s_1, s_2) \stackrel{a}{\dashrightarrow} (t_1, t_2)$ in $\mathcal{D}_1 \wedge \mathcal{D}_2$.

Let $(s_1, s_2) \longrightarrow N$ in $\mathcal{D}_1 \wedge \mathcal{D}_2$. By construction, N is such that either (1) there exists N_1 such that $s_1 \longrightarrow N_1$ in \mathcal{D}_1 and $N = \{(a, (t_1, t_2)) \mid (a, t_1) \in N_1, (s_1, s_2) \stackrel{a}{\dashrightarrow} (t_1, t_2)\}$, or (2) there exists N_2 such that $s_2 \longrightarrow N_2$ in \mathcal{D}_2 and $N = \{(a, (t_1, t_2)) \mid (a, t_2) \in N_2, (s_1, s_2) \stackrel{a}{\dashrightarrow} (t_1, t_2)\}$. Assume that (1) holds (case

(2) being symmetric). Since $M_1 \in \text{Tran}_1(s_1)$, there must be $(a, t_1) \in N_1 \cap M_1$. As $\pi_1(M) = M_1$, there must be $t_2 \in S_2$ such that $(a, (t_1, t_2)) \in M$. As a consequence, there is $(a, (t_1, t_2)) \in M \cap N$.

We have shown that $M \in \operatorname{Tran}^{\wedge}(s_1, s_2)$. Similarly, we can show that for all $M \in \operatorname{Tran}^{\wedge}(s_1, s_2)$, we also have $M \in \operatorname{Tran}_{\wedge}(s_1, s_2)$. We can thus conclude that $\operatorname{Tran}^{\wedge} = \operatorname{Tran}_{\wedge}$, hence $\mathcal{A}^{\wedge} = \mathcal{A}_{\wedge}$.

Theorem 20. For all specifications S_1 , S_2 , S_3 ,

- $S_1 \vee S_2 \leq_m S_3$ iff $S_1 \leq_m S_3$ and $S_2 \leq_m S_3$,
- $S_1 \leq_{\mathsf{m}} S_2 \wedge S_3$ iff $S_1 \leq_{\mathsf{m}} S_2$ and $S_1 \leq_{\mathsf{m}} S_3$,
- $[S_1 \vee S_2] = [S_1] \cup [S_2]$, and $[S_1 \wedge S_2] = [S_1] \cap [S_2]$.

PROOF. The proof falls into six parts. We show the second statement of the theorem separately for DMTS and for NAA. For the other formalisms, the statement then follows by structural equivalence.

- $S_1 \vee S_2 \leq_{\mathsf{m}} S_3$ iff $S_1 \leq_{\mathsf{m}} S_3$ and $S_2 \leq_{\mathsf{m}} S_3$: Any modal refinement $R \subseteq (S_1 \cup S_2) \times S_3$ splits into two refinements $R_1 \subseteq S_1 \times S_3$, $R_2 \subseteq S_2 \times S_3$ and vice versa.
- $\bullet \ \mathcal{S}_1 \leq_m \mathcal{S}_2 \wedge \mathcal{S}_3 \ \text{is implied by} \ \mathcal{S}_1 \leq_m \mathcal{S}_2 \ \text{and} \ \mathcal{S}_1 \leq_m \mathcal{S}_3 \text{:}$

We first show this proof for DMTS. Let $S_i = (S_i, S_i^0, -- \cdot_i, \longrightarrow_i)$, for i = 1, 2, 3, be DMTS and $R_2 \subseteq S_1 \times S_2$, $R_3 \subseteq S_1 \times S_3$ modal refinements and define $R = \{(s_1, (s_2, s_3)) \mid (s_1, s_2) \in R_1, (s_1, s_3) \in R_3\} \subseteq S_1 \times (S_2 \times S_3)$. Then R is initialised.

Now let $(s_1, (s_2, s_3)) \in R$, then $(s_1, s_2) \in R_2$ and $(s_1, s_3) \in R_3$. Assume that $s_1 \stackrel{a}{\dashrightarrow}_1 t_1$, then by $S_1 \leq_{\mathsf{m}} S_2$, we have $s_2 \stackrel{a}{\dashrightarrow}_2 t_2$ with $(t_1, t_2) \in R_2$. Similarly, by $S_1 \leq_{\mathsf{m}} S_3$, we have $s_3 \stackrel{a}{\dashrightarrow}_3 t_3$ with $(t_1, t_3) \in R_3$. But then also $(t_1, (t_2, t_3)) \in R$, and $(s_2, s_3) \stackrel{a}{\dashrightarrow}_3 (t_2, t_3)$ by definition.

Assume that $(s_2,s_3) \longrightarrow N$. Without loss of generality we can assume that there is $s_2 \longrightarrow_2 N_2$ such that $N = \{(a,(t_2,t_3)) \mid (a,t_2) \in N_2, s_3 \stackrel{a}{\dashrightarrow}_3 t_3\}$. By $S_1 \leq_{\mathsf{m}} S_2$, we have $s_1 \longrightarrow_1 N_1$ such that

$$\forall (a, t_1) \in N_1 : \exists (a, t_2) \in N_2 : (t_1, t_2) \in R_2 \tag{5}$$

Let $(a, t_1) \in N_1$, then also $s_1 \xrightarrow{a} t_1$, so by $S_1 \leq_{\mathsf{m}} S_3$, there is $s_3 \xrightarrow{a} t_3$ with $(t_1, t_3) \in R_3$. By (5), we also have $(a, t_2) \in N_2$ such that $(t_1, t_2) \in R_2$, but then $(a, (t_2, t_3)) \in N$ and $(t_1, (t_2, t_3)) \in R$.

 $\bullet \ \mathcal{S}_1 \leq_{\mathsf{m}} \mathcal{S}_2 \wedge \mathcal{S}_3 \ \mathit{implies} \ \mathcal{S}_1 \leq_{\mathsf{m}} \mathcal{S}_2 \ \mathit{and} \ \mathcal{S}_1 \leq_{\mathsf{m}} \mathcal{S}_3 \colon$

Let $R \subseteq S_1 \times (S_2 \times S_3)$ be a (DMTS) modal refinement. We show that $S_1 \leq_{\mathsf{m}} S_2$, the proof of $S_1 \leq_{\mathsf{m}} S_3$ being entirely analogous. Define $R_2 = \{(s_1, s_2) \mid \exists s_3 \in S_3 : (s_1, (s_2, s_3)) \in R\} \subseteq S_1 \times S_2$, then R_2 is initialised.

Let $(s_1, s_2) \in R_2$, then we must have $s_3 \in S_3$ such that $(s_1, (s_2, s_3)) \in R$. Assume that $s_1 \stackrel{a}{\dashrightarrow} t_1$, then also $(s_2, s_3) \stackrel{a}{\dashrightarrow} (t_2, t_3)$ and $(t_1, (t_2, t_3)) \in R$. By construction we have $s_2 \stackrel{a}{\dashrightarrow} t_2$ and $s_3 \stackrel{a}{\dashrightarrow} t_3$. Moreover, by definition of R_2 , $(t_1, t_2) \in R_2$.

Assume that $s_2 \longrightarrow_2 N_2$, then by construction of $\mathcal{S}_2 \wedge \mathcal{S}_3$, $(s_2, s_3) \longrightarrow N = \{(a, (t_2, t_3)) \mid (a, t_2) \in N_2, s_3 \stackrel{a}{\dashrightarrow}_3 t_3\}$. By $\mathcal{S}_1 \leq_{\mathsf{m}} \mathcal{S}_2 \wedge \mathcal{S}_3$, we have $s_1 \longrightarrow_1 N_1$ such that $\forall (a, t_1) \in N_1 : \exists (a, (t_2, t_3)) \in N : (t_1, (t_2, t_3)) \in R$.

Let $(a, t_1) \in N_1$, then we have $(a, (t_2, t_3)) \in N$ for which $(t_1, (t_2, t_3)) \in R$. By construction of N, this implies that there are $(a, t_2) \in N_2$ and $s_3 \xrightarrow{a} t_3$. Moreover, by definition of R_2 , $(t_1, t_2) \in R$.

• $A_1 \leq_m A_2 \wedge A_3$ is implied by $A_1 \leq_m A_2$ and $A_1 \leq_m A_3$:

Now we show the second part of the lemma for NAA. Let $\mathcal{A}_i = (\mathcal{S}_i, \mathcal{S}_i^0, \operatorname{Tran}_i)$, for i = 1, 2, 3, be NAA and $R_2 \subseteq S_1 \times S_2$, $R_3 \subseteq S_1 \times S_3$ modal refinements and define $R = \{(s_1, (s_2, s_3)) \mid (s_1, s_2) \in R_1, (s_1, s_3) \in R_3\} \subseteq S_1 \times (S_2 \times S_3)$. Then R is initialised.

Let $(s_1,(s_2,s_3)) \in R$, then $(s_1,s_2) \in R_2$ and $(s_1,s_3) \in R_3$. Let $M_1 \in \operatorname{Tran}_1(s_1)$, then we have $M_2 \in \operatorname{Tran}_2(s_2)$ and $M_3 \in \operatorname{Tran}_3(s_3)$ such that the pairs M_1, M_2 and M_1, M_3 verify the conditions (2) in Definition 7. Let $M = \{(a,(t_2,t_3)) \mid (a,t_2) \in M_2, (a,t_3) \in M_3\} \subseteq \Sigma \times S$.

We show that $\pi_2(M) = M_2$ and, similarly, $\pi_3(M) = M_3$: It is clear that $\pi_2(M) \subseteq M_2$, so let $(a, t_2) \in M_2$. By the refinement R_2 , there is $(a, t_1) \in M_1$, so by the refinement R_3 , there is $(a, t_3) \in M_3$, but then $(a, t_2) \in \pi_2(M)$. Using $\pi_2(M) = M_2$ and $\pi_3(M) = M_3$, we can now conclude that $M \in \text{Tran}((s_2, s_3))$.

Let $(a, t_1) \in M_1$, then we have $(a, t_2) \in M_2$ and $(a, t_3) \in M_3$ such that $(t_1, t_2) \in R_2$ and $(t_1, t_3) \in R_3$. But then $(t_1, (t_2, t_3)) \in R$ and $(a, (t_2, t_3)) \in M$.

Let $(a, (t_2, t_3)) \in M$, then $(a, t_2) \in M_2$ and $(a, t_3) \in M_3$. By the refinements R_2 and R_3 , we have $(a, t_1) \in M_1$ such that $(t_1, t_2) \in R_2$ and $(t_1, t_3) \in R_3$, but then also $(t_1, (t_2, t_3)) \in R$.

• $A_1 \leq_{\mathsf{m}} A_2 \wedge A_3$ implies $A_1 \leq_{\mathsf{m}} A_2$ and $A_1 \leq_{\mathsf{m}} A_3$:

Let $R \subseteq S_1 \times (S_2 \times S_3)$ be a (NAA) modal refinement. We show that $A_1 \leq_m A_2$; the proof of $A_1 \leq_m A_3$ is similar. Define $R_2 = \{(s_1, s_2) \mid \exists s_3 \in S_3 : (s_1, (s_2, s_3)) \in R\} \subseteq S_1 \times S_2$, then R_2 is initialised.

Let $(s_1, s_2) \in R_2$, then there is $t_3 \in S_3$ with $(t_1, (t_2, t_3)) \in R$. Let $M_1 \in \text{Tran}_1(s_1)$, then we have $M \in \text{Tran}((s_2, s_3))$ such that the pair M_1, M satisfies conditions (2). Let $M_2 = \pi_2(M) \in \text{Tran}_2(s_2)$.

Let $(a, t_1) \in M_1$, then there is $(a, (t_2, t_3)) \in M$ such that $(t_1, (t_2, t_3)) \in R$; hence $(t_1, t_2) \in R$ and $(a, t_2) \in M_2$.

Let $(a, t_2) \in M_2$, then there is $t_3 \in S_3$ such that $(a, (t_2, t_3)) \in M$. But then we also have $(a, t_1) \in M_1$ such that $(t_1, (t_2, t_3)) \in R$, thus $(t_1, t_2) \in R_2$.

• $\llbracket \mathcal{S}_1 \vee \mathcal{S}_2 \rrbracket = \llbracket \mathcal{S}_1 \rrbracket \cup \llbracket \mathcal{S}_2 \rrbracket$ and $\llbracket \mathcal{S}_1 \wedge \mathcal{S}_2 \rrbracket = \llbracket \mathcal{S}_1 \rrbracket \cap \llbracket \mathcal{S}_2 \rrbracket$:

 $\llbracket \mathcal{S}_1 \wedge \mathcal{S}_2 \rrbracket = \llbracket \mathcal{S}_1 \rrbracket \cap \llbracket \mathcal{S}_2 \rrbracket$ is clear from what we just proved: for all implementations $\mathcal{I}, \mathcal{I} \leq_{\mathsf{m}} \mathcal{S}_1 \wedge \mathcal{S}_2$ iff $\mathcal{I} \leq_{\mathsf{m}} \mathcal{S}_1$ and $\mathcal{I} \leq_{\mathsf{m}} \mathcal{S}_2$. For the other part, it is clear by construction that for any implementation \mathcal{I} , any witness R for $\mathcal{I} \leq_{\mathsf{m}} \mathcal{S}_1$ is also a witness for $\mathcal{I} \leq_{\mathsf{m}} \mathcal{S}_1 \vee \mathcal{S}_2$, and similarly for \mathcal{S}_2 , hence $\llbracket \mathcal{S}_1 \rrbracket \cup \llbracket \mathcal{S}_2 \rrbracket \subseteq \llbracket \mathcal{S}_1 \vee \mathcal{S}_2 \rrbracket$.

To show the other inclusion, we note that an initialised refinement R witnessing $\mathcal{I} \leq_{\mathsf{m}} \mathcal{S}_1 \vee \mathcal{S}_2$ must relate the initial state of \mathcal{I} either to an initial state of \mathcal{S}_1 or to an initial state of \mathcal{S}_2 . In the first case, and by disjointness, R witnesses $\mathcal{I} \leq_{\mathsf{m}} \mathcal{S}_1$, in the second, $\mathcal{I} \leq_{\mathsf{m}} \mathcal{S}_2$. Note how it is essential here that *implementations* have but *one* initial state; this part of the proof would break down if we were to allow several initial states for implementations.

Corollary 21. With operations \vee and \wedge , each of our four classes of specifications forms a bounded distributive lattice up to \equiv_m .

PROOF. The bottom elements (up to \equiv_m) in the lattices are given by specifications with empty initial state sets. The top elements are the DMTS

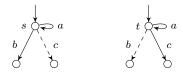

Figure 9: DMTS S and T whose composition cannot be captured precisely

 $(\{s^0\}, \{s^0\}, \{(s^0, a, s^0) \mid a \in \Sigma\}, \emptyset)$ and its respective translations. The other lattice properties follow from Theorem 20.

We miss to verify distributivity. Let $\mathcal{A}_i = (S_i, S_i^0, \operatorname{Tran}_i)$, for i = 1, 2, 3, be NAA. The set of states of both $\mathcal{A}_1 \wedge (\mathcal{A}_2 \vee \mathcal{A}_3)$ and $(\mathcal{A}_1 \wedge \mathcal{A}_2) \vee (\mathcal{A}_1 \wedge \mathcal{A}_3)$ is $S_1 \times (S_2 \cup S_3) = S_1 \times S_2 \cup S_1 \times S_3$, and one easily sees that the identity relation is a two-sided modal refinement. Things are similar for the other distributive law.

4.2. Composition

The composition operator for a specification theory is to mimic, at specification level, the parallel composition of implementations. That is to say, if \parallel is a composition operator for implementations (LTS), then the goal is to extend \parallel to specifications such that for all specifications S_1 , S_2 ,

$$\llbracket \mathcal{S}_1 \Vert \mathcal{S}_2 \rrbracket = \{ \mathcal{I}_1 \Vert \mathcal{I}_2 \mid \mathcal{I}_1 \in \llbracket \mathcal{S}_1 \rrbracket, \mathcal{I}_2 \in \llbracket \mathcal{S}_2 \rrbracket \}. \tag{6}$$

For simplicity, we use CSP-style synchronisation for parallel composition of LTS, however, our results readily carry over to other types of composition. Analogously to the situation for MTS [10], we have the following negative result:

Theorem 22. There is no operator \parallel , for any of our specification formalisms, which satisfies (6).

PROOF. We show that there exist DMTS \mathcal{S} and \mathcal{T} such that there is no DMTS \mathcal{D} with $\llbracket \mathcal{D} \rrbracket = \llbracket \mathcal{S} \rrbracket \rVert \llbracket \mathcal{T} \rrbracket \coloneqq \{ \mathcal{I} \lVert \mathcal{J} \mid \mathcal{I} \in \llbracket \mathcal{S} \rrbracket, \mathcal{J} \in \llbracket \mathcal{T} \rrbracket \}$. They are given in Figure 9; \mathcal{S} has initial state s, while \mathcal{T} has initial state t. Note that in fact, \mathcal{S} and \mathcal{T} are MTS, i.e. no disjunctive must transitions are used.

We make the following observations about implementations of \mathcal{S} and \mathcal{T} . They always admit one or more infinite runs labelled with a's with one-step b or c branches. Moreover, all infinite runs in these implementations are of this form. To each infinite a-run of an implementation we assign its signature, that is a word over $2^{\{b,c\}}$ that describes which one-step branches are available at each step. This means that every implementation of \mathcal{S} has runs with signatures from $\{\{b\},\{b,c\}\}^{\omega}$, while every implementation of \mathcal{T} has runs with signatures from $\{\{c\},\{b,c\}\}^{\omega}$.

We now construct an implementation state space as illustrated in Figure 10. Consider the implementations $\mathcal{I}_1, \mathcal{I}_2, \ldots$ that share the same state space and have the initial state i_1, i_2, \ldots , respectively. The implementation \mathcal{I}_n has only one a-run with the signature $\emptyset^n\{b,c\}\emptyset^\omega$. Note that \mathcal{I}_n is the composition of an implementation of \mathcal{S} that has only one a-run with the signature $\{b\}^n\{b,c\}\{b\}^\omega$ and an implementation of \mathcal{T} that has only one a-run with the signature $\{c\}^n\{b,c\}\{c\}^\omega$.

Assume now that there exists a DMTS \mathcal{D} with $[\![\mathcal{D}]\!] = [\![\mathcal{S}]\!] + [\![\mathcal{T}]\!]$. As all \mathcal{I}_n belong to $[\![\mathcal{D}]\!]$ and there is only a finite number of initial states of \mathcal{D} , there

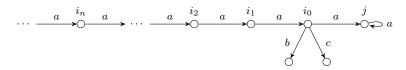

Figure 10: Implementation state space illustrating the proof of Theorem 22

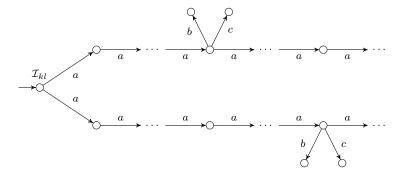

Figure 11: The nondeterministic sum of \mathcal{I}_k and \mathcal{I}_l , unfolded

has to be at least one initial state of \mathcal{D} , say d, such that there exists a modal refinement R containing both (i_k,d) and (i_l,d) for some numbers k < l. Let \mathcal{D}_d be created from \mathcal{D} by changing the set of initial states to the singleton $\{d\}$. As both $\mathcal{I}_k \leq_{\mathsf{m}} \mathcal{D}_d$ and $\mathcal{I}_l \leq_{\mathsf{m}} \mathcal{D}_d$ and \mathcal{D}_d has only one initial state, we know by Lemma 17 that also $\mathcal{I}_{kl} = \mathcal{I}_k + \mathcal{I}_l \leq_{\mathsf{m}} \mathcal{D}_d$. The unfolding of this implementation is illustrated in Figure 11.

We now argue that $\mathcal{I}_{kl} \notin \llbracket \mathcal{S} \rrbracket \Vert \llbracket \mathcal{T} \rrbracket$. We actually show that it cannot even be bisimilar to any $\mathcal{I} \Vert \mathcal{J}$ with $\mathcal{I} \in \llbracket \mathcal{S} \rrbracket$ and $\mathcal{J} \in \llbracket \mathcal{T} \rrbracket$. Let us assume that there exist such \mathcal{I} and \mathcal{J} . We make the following observations:

- \mathcal{I} has to contain at least one a-run with signature $\{b\}^k \{b,c\} \{b\}^{\omega}$. Otherwise, it would be impossible to create the \mathcal{I}_k part of \mathcal{I}_{kl} .
- \mathcal{J} has to contain at least one a-run with signature $\{c\}^l\{b,c\}\{c\}^{\omega}$. Otherwise, it would be impossible to create the \mathcal{I}_l part of \mathcal{I}_{kl} .

However, these observations mean that $\mathcal{I} \| \mathcal{J}$ contains at least one a-run with signature $\emptyset^k \{c\} \emptyset^{l-k-1} \{b\} \emptyset^{\omega}$. It is thus not bisimilar to \mathcal{I}_{kl} .

Given that we cannot have (6), the revised goal is to have a *sound* composition operator for which the right-to-left inclusion holds in (6). For NAA $\mathcal{A}_1 = (S_1, S_1^0, \operatorname{Tran}_1)$, $\mathcal{A}_2 = (S_2, S_2^0, \operatorname{Tran}_2)$, we define $\mathcal{A}_1 \| \mathcal{A}_2 = (S, S^0, \operatorname{Tran})$ with $S = S_1 \times S_2$, $S^0 = S_1^0 \times S_2^0$, and for all $(s_1, s_2) \in S$, $\operatorname{Tran}(s_1, s_2) = \{M_1 \| M_2 \| M_1 \in \operatorname{Tran}_1(s_1), M_2 \in \operatorname{Tran}_2(s_2)\}$, where $M_1 \| M_2 = \{(a, (t_1, t_2)) | (a, t_1) \in M_1, (a, t_2) \in M_2\}$. Composition for DMTS is defined using the translations to and from NAA; note that this may incur an exponential blow-up.

Lemma 23. Up to \equiv_m , the operator \parallel on NAA is associative and commutative, distributes over \vee , and has unit \cup , where \cup is the LTS $(\{s\}, s, \longrightarrow)$ with $s \stackrel{a}{\longrightarrow} s$ for all $a \in \Sigma$.

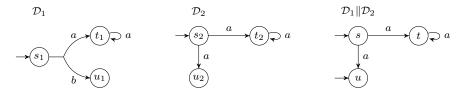

Figure 12: Two DMTS and the reachable parts of the DMTS translation of their composition. Here, $s = \{(a, (t_1, t_2)), (a, (t_1, u_2))\}$, $t = \{(a, (t_1, t_2))\}$ and $u = \emptyset$

PROOF. Associativity and commutativity are clear. To show distributivity over \vee , let $\mathcal{A}_i = (S_i, S_i^0, \operatorname{Tran}_i)$, for i = 1, 2, 3, be NAA. We prove that $\mathcal{A}_1 \| (\mathcal{A}_1 \vee \mathcal{A}_3) \equiv_{\mathfrak{m}} \mathcal{A}_1 \| \mathcal{A}_2 \vee \mathcal{A}_1 \| \mathcal{A}_3$; right-distributivity will follow by commutativity. The state spaces of both sides are $S_1 \times S_2 \cup S_1 \times S_3$, and it is easily verified that the identity relation is a two-sided modal refinement.

For the claim that $\mathcal{A} \| \mathsf{U} \equiv_{\mathsf{m}} \mathcal{A}$ for all NAA $\mathcal{A} = (S, S^0, \operatorname{Tran})$, let u be the unique state of U and define $R = \{((s,u),s) \mid s \in S\} \subseteq S \times \mathsf{U} \times S$. We show that R is a two-sided modal refinement. Let $((s,u),s) \in R$ and $M \in \operatorname{Tran}(s,u)$, then there must be $M_1 \in \operatorname{Tran}(s)$ for which $M = M_1 \| (\Sigma \times \{u\})$. Thus $M_1 = \{(a,t) \mid (a,(t,u)) \in M\}$. Then any element of M has a corresponding one in M_1 , and vice versa, and their states are related by R. For the other direction, let $M_1 \in \operatorname{Tran}(s)$, then $M = M_1 \| (\Sigma \times \{u\}) = \{(a,(t,u)) \mid (a,t) \in M_1\} \in \operatorname{Tran}(s,u)$, and the same argument applies. \square

The next theorem is one of *independent implementability*, as it ensures that a composition of refinements is a refinement of compositions:

Theorem 24. For all specifications S_1 , S_2 , S_3 , S_4 , $S_1 \leq_m S_3$ and $S_2 \leq_m S_4$ imply $S_1 \| S_2 \leq_m S_3 \| S_4$.

PROOF. Let $S_1 \leq_m S_3$ and $S_2 \leq_m S_4$, then $S_1 \vee S_3 \equiv_m S_3$ and $S_2 \vee S_4 \equiv_m S_4$. By distributivity,

$$S_3 \| S_4 \equiv_{\mathsf{m}} (S_1 \vee S_3) \| (S_2 \vee S_4)$$
$$\equiv_{\mathsf{m}} S_1 \| S_2 \vee S_1 \| S_4 \vee S_3 \| S_2 \vee S_3 \| S_4.$$

thus

$$\mathcal{S}_1 \| \mathcal{S}_2 \vee \mathcal{S}_1 \| \mathcal{S}_4 \vee \mathcal{S}_3 \| \mathcal{S}_2 \leq_{\mathsf{m}} \mathcal{S}_3 \| \mathcal{S}_4 .$$

But

$$\mathcal{S}_1 \| \mathcal{S}_2 \leq_{\mathsf{m}} \mathcal{S}_1 \| \mathcal{S}_2 \vee \mathcal{S}_1 \| \mathcal{S}_4 \vee \mathcal{S}_3 \| \mathcal{S}_2 \,,$$

finishing the argument.

Example 3. An example of composition is shown in Fig. 12. Here the DMTS translation of $\mathcal{D}_1 \| \mathcal{D}_2$ has two initial states; it can be shown that no DMTS with a single initial state is thoroughly equivalent.

Remark that NAA composition is more precise than the composition for MTS introduced in [40]. The MTS composition is given by the following rules: $(s_1, s_2) \stackrel{a}{\dashrightarrow} (t_1, t_2)$ whenever $s_1 \stackrel{a}{\dashrightarrow} t_1$ and $s_2 \stackrel{a}{\dashrightarrow} t_2$, $(s_1, s_2) \stackrel{a}{\longrightarrow} (t_1, t_2)$ whenever $s_1 \stackrel{a}{\longrightarrow} t_1$ and $s_2 \stackrel{a}{\longrightarrow} t_2$. The difference between the two compositions is

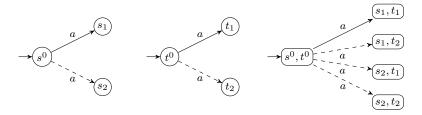

Figure 13: Two MTS and their MTS composition according to [40]

illustrated in Fig. 13. The figure shows two MTS and their MTS composition; for their NAA composition,

$$\operatorname{Tran}(s^{0}, t^{0}) = \{\{(a, (s_{1}, t_{1}))\}, \{(a, (s_{1}, t_{1})), (a, (s_{1}, t_{2}))\}, \{(a, (s_{1}, t_{1})), (a, (s_{2}, t_{1}))\}, \{(a, (s_{1}, t_{1})), (a, (s_{1}, t_{2})), (a, (s_{2}, t_{1})), (a, (s_{2}, t_{2}))\}\}.$$
(7)

The NAA translation of their MTS composition has eight transition constraints instead of four; note how the four constraints in (7) precisely correspond to the four implementation choices for s^0 and t^0 .

It can easily be shown that generally, NAA composition is a refinement of MTS composition. The following lemma shows a stronger relationship, namely that the MTS composition is a conservative approximation of the NAA composition.

Lemma 25. Let \mathcal{M}_1 , \mathcal{M}_2 , \mathcal{M}_3 be MTS and let $\|_{M}$ and $\|_{A}$ be the MTS and NAA composition, respectively. It holds that $\mathcal{M}_1\|_{M}\mathcal{M}_2 \leq_{\mathsf{m}} \mathcal{M}_3$ iff $\mathcal{M}_1\|_{A}\mathcal{M}_2 \leq_{\mathsf{m}} \mathcal{M}_3$.

PROOF. Let $\mathcal{M}_i = (S_i^0, \{s_i^0\}, -- \cdot_i, \longrightarrow_i)$ be MTS for i = 1, 2, 3. In the following, we use the notation $s_1 \parallel_A s_2$ to denote the states (s_1, s_2) of $\mathcal{M}_1 \parallel_A \mathcal{M}_2$ and similarly for \parallel_M .

For an MTS translated into NAA, the Tran sets have a special structure, namely, for all states s, $\operatorname{Tran}(s)$ always has a maximal element $\{(a,t) \mid s \stackrel{a}{\longrightarrow} t\}$ and a minimal element $\{(a,t) \mid s \stackrel{a}{\longrightarrow} t\}$ (with respect to set inclusion; cf. Lemma 14 for the similar property for DMTS). Furthermore, we note that $\operatorname{Tran}(s_1|_{A}s_2) \subseteq \operatorname{Tran}(s_1|_{M}s_2)$ and, moreover, $\operatorname{Tran}(s_1|_{A}s_2)$ also has a minimal and a maximal element and these elements correspond to the minimal and maximal element of $\operatorname{Tran}(s_1|_{M}s_2)$.

The fact that $\mathcal{M}_1 \|_{\mathcal{A}} \mathcal{M}_2 \leq_{\mathsf{m}} \mathcal{M}_1 \|_{\mathcal{M}} \mathcal{M}_2$ follows from the observation that $\operatorname{Tran}(s_1 \|_{\mathcal{A}} s_2) \subseteq \operatorname{Tran}(s_1 \|_{\mathcal{M}} s_2)$ for all (s_1, s_2) . This proves the 'only-if' part of the lemma.

To prove the 'if' part of the lemma, we let $R = \{(s_1|_{\mathbb{M}}s_2, s_3) \mid s_1|_{\mathbb{A}}s_2 \leq_{\mathsf{m}} s_3\}$ and show that it is a modal refinement relation witnessing $\mathcal{M}_1|_{\mathbb{M}}\mathcal{M}_2 \leq_{\mathsf{m}} \mathcal{M}_3$. Let $(s_1|_{\mathbb{M}}s_2, s_3) \in R$.

• Let $s_1 \|_{M} s_2 \xrightarrow{a} t_1 \|_{M} t_2$. Then $(a, t_1 \|_{M} t_2)$ belongs to the maximal element of $\operatorname{Tran}(s_1 \|_{M} s_2)$, which is also in $\operatorname{Tran}(s_1 \|_{A} s_2)$. Due to $s_1 \|_{A} s_2 \leq_{\mathsf{m}} s_3$ we have some $N \in \operatorname{Tran}(s_3)$ with $(a, t_3) \in N$ such that $t_1 \|_{A} t_2 \leq_{\mathsf{m}} t_3$. Thus $s_3 \xrightarrow{a} t_3$ and $(t_1 \|_{M} t_2, t_3) \in R$.

• Let $s_3 \stackrel{a}{\longrightarrow} t_3$. Then all elements of $\operatorname{Tran}(s_3)$ contain (a,t_3) . If we now chose the minimal element $M \in \operatorname{Tran}(s_1||_A s_2)$ then it has to contain $(a,t_1||_A t_2)$ such that $(t_1||_A t_2 \leq_m t_3)$. This means that $s_1||_M s_2 \stackrel{a}{\longrightarrow} t_1||_M t_2$ and $(t_1||_M t_2,t_3) \in R$.

4.3. Quotient

The quotient operator for a specification theory is used to synthesise specifications for components of a composition. Hence it is to have the property, for all specifications \mathcal{S} , \mathcal{S}_1 and all implementations \mathcal{I}_1 , \mathcal{I}_2 , that

$$\mathcal{I}_1 \in \llbracket \mathcal{S}_1 \rrbracket \text{ and } \mathcal{I}_2 \in \llbracket \mathcal{S}/\mathcal{S}_1 \rrbracket \text{ imply } \mathcal{I}_1 \Vert \mathcal{I}_2 \in \llbracket \mathcal{S} \rrbracket.$$
 (8)

Furthermore, S/S_1 is to be as permissive as possible.

4.3.1. Quotient for MTS

Before we describe the general construction of the quotient, we start with a simpler construction that works for the important special case of MTS. However, MTS are not closed under quotient, *cf.* [41, Thm. 5.5]; we show that the quotient of two MTS will generally be a DMTS.

Recall that MTS have only one initial state and all their must transitions are singletons. Let $\mathcal{M}_1 = (S_1, s_1^0, -\rightarrow_1, \longrightarrow_1)$ and $\mathcal{M}_2 = (S_2, s_2^0, -\rightarrow_2, \longrightarrow_2)$ be MTS. We define $\mathcal{M}_1/\mathcal{M}_2 = (S, s^0, -\rightarrow, \longrightarrow)$ with $S = 2^{S_1 \times S_2}$, $s^0 = \{(s_1^0, s_2^0)\}$, and the transition relations given as follows.

For $s=\{(s_1^1,s_2^1),\ldots,(s_1^n,s_2^n)\}\in S$ we say that $a\in\Sigma$ is permissible from s if for all $i=1,\ldots,n$ either $s_1^i\overset{a}{\dashrightarrow}$ or $s_2^i\overset{a}{\rightarrowtail}$. For a permissible from s and $i\in\{1,\ldots,n\}$, let $\{t_2^{i,1},\ldots,t_2^{i,m_i}\}=\{t_2\in S_2\mid s_1^i,\ldots,s_n^i\}$

For a permissible from s and $i \in \{1, ..., n\}$, let $\{t_2^{i,1}, ..., t_2^{i,m_i}\} = \{t_2 \in S_2 \mid s_2^{i} \xrightarrow{a} t_2\}$ be an enumeration of the possible states in S_2 after an a-transition from s_2^{i} . We then define the set of possible transitions from s under s as s_2^{i} and s_3^{i} are s_3^{i} are s_3^{i} and s_3^{i} and s_3^{i} are s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} are s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} and s_3^{i} are s_3^{i} and s_3^{i} are $s_3^$

 $\begin{array}{l} pt_a(s) = \left\{ \left\{ (t_1^{i,j}, t_2^{i,j}) \mid i = 1, \ldots, n, j = 1, \ldots, m_i \right\} \mid \forall i, j : s_1^i \stackrel{a}{\dashrightarrow} t_1^{i,j} \right\}. \\ \text{The transitions of } s \text{ are now given as follows: for every } a \text{ permissible from } s \text{ and every } t \in pt_a(s), \text{ let } s \stackrel{a}{\dashrightarrow} t. \end{array} \right. \\ \text{Furthermore, for every } s_1^i \stackrel{a}{\longrightarrow} t_1 \text{ let } s \longrightarrow \left\{ (a, M) \in \{a\} \times pt_a(s) \mid \exists t_2 : (t_1, t_2) \in M, s_2^i \stackrel{a}{\longrightarrow} t_2 \right\}. \end{array}$

Note that as a special case we obtain $\emptyset \xrightarrow{a} \emptyset$ for all $a \in \Sigma$ and there are no must transitions from \emptyset .

Example 4. We illustrate the construction on an example. Let S and T be the MTS on the top of Fig. 14. We construct S/T, displayed below; this can be further simplified into the system on the bottom.

First we construct the may-successors of s^0/t^0 . Both b and c are admissible due to $t^0 \stackrel{b}{\not\longrightarrow}$ and $t^0 \stackrel{c}{\not\longrightarrow}$ and thus with $pt(_)b(s^0/t^0) = pt(_)c(s^0/t^0) = \{\emptyset\}$. Consequently, the only successor here is \emptyset . Further, a is also admissible due to $s^0 \stackrel{a}{\longrightarrow}$. For may-transitions under a, we have to consider all mappings of successors of t^0 to successors of s^0 , namely $\{s_1/t_1, s_1/t_2\}$, $\{s_1/t_1, s_2/t_2\}$, $\{s_2/t_1, s_1/t_2\}$, and $\{s_2/t_1, s_2/t_2\}$. Besides, since there is a must-transition from s^0 (to s_1), we create a disjunctive must-transition to all successors that can be used to yield this must-transition $s^0 \stackrel{a}{\longrightarrow} s_1$ when composed with the must-transition $t^0 \stackrel{a}{\longrightarrow} t_1$. These are all successors where t_1 is mapped to s_1 , hence the first two.

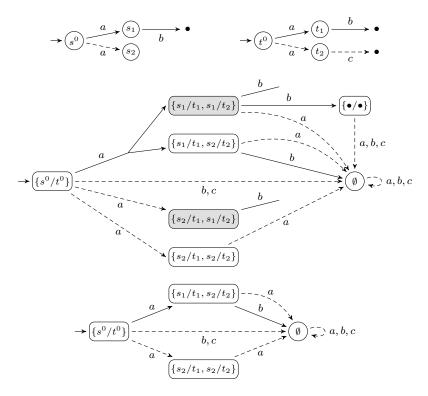

Figure 14: Two nondeterministic MTS, their quotient, and its simplification by pruning

Further, $\{s_1/t_1, s_2/t_2\}$ is obliged to have a must under b so that it refines s_1 when composed with t_1 , but cannot have any c in order to match s_2 when composed with t_2 . Similarly, $\{s_2/t_1, s_2/t_2\}$ has neither c nor b.

composed with t_2 . Similarly, $\{s_2/t_1, s_2/t_2\}$ has neither c nor b.

The first and third successor of s^0/t^0 deserve special attention. Firstly, $\{s_1/t_1, s_1/t_2\}$ has (apart from a may-transition under a) transitions under b: may to $\{\bullet/\bullet\}$ and two musts. Both musts are due to s_1 , but the first one because of s_1 in s_1/t_1 (leading to $\{\bullet/\bullet\}$) and the second one because of s_1 in s_1/t_2 (leading to an empty disjunction because $t_2 \not\longrightarrow$). The empty disjunction is drawn as a line not branching anywhere. Note that it is very different from a may-transition to \emptyset and cannot be implemented. States with such a transition are drawn in gray here and called inconsistent.

Secondly, $\{s_2/t_1, s_1/t_2\}$ is inconsistent for the same reason: it requires to refine s_1 by a composition with t_2 . As t_2 has no must under b, the composition has none either, hence the must of s_1 can never be matched.

We have seen that the construction may produce empty must-disjunctions and thus also inconsistent states, i.e., states s such that $s \longrightarrow \emptyset$. Since inconsistent states have no implementations, their presence in the system is useless and we can remove them from the system using the procedure of *pruning*. This procedure produces a more readable system that has the same set of implementations and, moreover, is modally refining the original system. The procedure is standard for MTS, see e.g. [5]; here we describe its straightforward adaptation for DMTS. The procedure exhaustively repeats the following: if there is an inconsistent state s, then remove it together with all its outgoing transitions (both may

and must) and incoming may-transitions, and each remaining must-transition $t \longrightarrow D$ is modified into $t \longrightarrow D \setminus (\Sigma \times \{s\})$; intuitively, we are removing the incoming must-branches (not the whole transitions). This may of course turn other states inconsistent and thus the procedure is repeated until there are no more inconsistent states.

Example 5. When we apply pruning to the quotient in the previous example, we obtain the system on the bottom of Fig. 14. Here the gray inconsistent states are removed and the disjunctive must from $\{s^0/t^0\}$ leads only to $\{s_1/t_1, s_2/t_2\}$. Now it is easy to see that $T||(S/T) \equiv_m S$ in this case.

Recall from Lemma 25 that the MTS composition is a conservative approximation to the NAA composition. This means that the following theorem holds regardless of which of the two compositions is used.

Theorem 26. For all MTS specifications \mathcal{M}_1 , \mathcal{M}_2 and \mathcal{M}_3 , $\mathcal{M}_1 \| \mathcal{M}_2 \leq_m \mathcal{M}_3$ iff $\mathcal{M}_2 \leq_m \mathcal{M}_3 / \mathcal{M}_1$.

PROOF. In this proof only, let || denote MTS composition.

Write $\mathcal{M}_i = (S_i, s_i^0, -\rightarrow_i, \longrightarrow_i)$ for i = 1, 2, 3. We use the following notation to help distinguish states of $\mathcal{M}_1 \| \mathcal{M}_2$ and $\mathcal{M}_3 / \mathcal{M}_1$. The states of $\mathcal{M}_1 \| \mathcal{M}_2$ are denoted by $s_1 \| s_2$ instead of (s_1, s_2) while the states of $\mathcal{M}_3 / \mathcal{M}_1$ are denoted by $\{s_3 / s_1, \ldots\}$ instead of $\{(s_3, s_1), \ldots\}$. We also note that for states of $\mathcal{M}_3 / \mathcal{M}_1$, $s \supseteq t$ implies $s \leq_m t$ due to the construction.

Now assume that $\mathcal{M}_2 \leq_{\mathsf{m}} \mathcal{M}_3/\mathcal{M}_1$ and let $R = \{(s_1 || s_2, s_3) \mid s_2 \leq_{\mathsf{m}} \{s_3/s_1\}\}$. We show that R is a witness for $\mathcal{M}_1 || \mathcal{M}_2 \leq_{\mathsf{m}} \mathcal{M}_3$, *i.e.* that it satisfies the conditions of Definition 2. Let $(s_1 || s_2, s_3) \in R$.

- Let $s_1 \| s_2 \xrightarrow{a} t_1 \| t_2$. As $s_2 \leq_{\mathsf{m}} \{s_3/s_1\}$ this means that $\{s_3/s_1\} \xrightarrow{a} \{t_3^1/t_1^1, \ldots, t_3^k/t_1^k\} = t$ and $t_2 \leq_{\mathsf{m}} t$. Due to the construction of $\{s_3/s_1\}$, we know that there is an index j for which $t_1^j = t_1$ and $s_3 \xrightarrow{a} t_3^j$. Let $t_3 = t_3^j$. As $t \supseteq \{t_3/t_1\}$, $t \leq_{\mathsf{m}} \{t_3/t_1\}$. Therefore, since $t_2 \leq_{\mathsf{m}} t$, we have $t_2 \leq_{\mathsf{m}} \{t_3/t_1\}$ and thus $(t_1 \parallel t_2, t_3) \in R$.
- Let $s_3 \stackrel{a}{\longrightarrow} t_3$. This means that $\{s_3/s_1\} \longrightarrow U = \{(a,u) \in \{a\} \times pt_a(\{s_3/s_1\}) \mid \exists t_1 : t_3/t_1 \in u, s_1 \stackrel{a}{\longrightarrow} t_1\}$. As $s_2 \leq_{\mathsf{m}} \{s_3/s_1\}$, we know that $s_2 \stackrel{a}{\longrightarrow} t_2$ and $t_2 \leq_{\mathsf{m}} u$ for some $(a,u) \in U$. Due to the construction of U we know that there exists t_1 such that $t_3/t_1 \in u$ with $s_1 \stackrel{a}{\longrightarrow} t_1$. Thus $s_1 \| s_2 \stackrel{a}{\longrightarrow} t_1 \| t_2$. Again, as $u \supseteq \{t_3/t_1\}$, $t_2 \leq_{\mathsf{m}} \{t_3/t_1\}$. Therefore, $(t_1 \parallel t_2, t_3) \in R$.

Assume, for the other direction of the proof, that $\mathcal{M}_1 \parallel \mathcal{M}_2 \leq_{\mathsf{m}} \mathcal{M}_3$. Define

$$R = \{(s_2, \{s_3^1/s_1^1, \dots, s_3^n/s_1^n\}) \mid \forall i = 1, \dots, n : s_1^i \parallel s_2 \leq_{\mathsf{m}} s_3^i\};$$

note that $(s_2, \emptyset) \in R$ for all $s_2 \in S_2$. We show that R is a witness for $\mathcal{M}_2 \leq_{\mathsf{m}} \mathcal{M}_3/\mathcal{M}_1$. Let $(s_2, s) \in R$ with $s = \{s_3^1/s_1^1, \ldots, s_3^n/s_1^n\}$.

• Let $s_2 \stackrel{a}{\longrightarrow} t_2$. If there is no i such that $s_1^i \stackrel{a}{\longrightarrow}$ then $s \stackrel{a}{\longrightarrow} \emptyset$ and $(t_2, \emptyset) \in R$. Otherwise, for each $i \in \{1, \dots, n\}$ and each $j \in \{1, \dots, m_i\}$ such that $s_1^i \stackrel{a}{\longrightarrow} t_1^{i,j}$ consider that we have $s_1^i ||s_2 \stackrel{a}{\longrightarrow} t_1^{i,j}||t_2$ and as $s_1^i ||s_2 \le_m s_3^i$ we

also have a corresponding $s_3^i \stackrel{a}{\dashrightarrow} t_3^{i,j}$ with $t_1^{i,j} || t_2 \leq_{\mathsf{m}} t_3^{i,j}$. We fix these $t_3^{i,j}$ for each i and j. Let $t = \{t_3^{i,j}/t_1^{i,j} \mid i \in \{1,\ldots,n\}, j \in \{1,\ldots,m_i\}\}$. Clearly, $s \stackrel{a}{\dashrightarrow} t$ and $(t_2,t) \in R$.

• Let $s \longrightarrow U$ (note that this means that $s \neq \emptyset$) and let $s_3^i \stackrel{a}{\longrightarrow} t_3^i$ be the corresponding must transition in the construction. As $s_1^i \| s_2 \leq_{\mathsf{m}} s_3^i$, this means that $s_2 \stackrel{a}{\longrightarrow} t_2$ and $s_1^i \stackrel{a}{\longrightarrow} t_1^i$ such that $t_1^i \| t_2 \leq_{\mathsf{m}} t_3^i$. This also means that $s_2 \stackrel{a}{\longrightarrow} t_2$. We thus build t as we did in the previous case where for i, j such that $t_1^{i,j} = t_1^i$ we choose the corresponding $t_3^{i,j}$ to be t_3^i . Clearly $(t_2, t) \in R$.

4.3.2. Quotient for NAA

We now introduce the general quotient operator for NAA. The construction is similar to the previous one, with the notions of permissibility and $pt_a(s)$ adapted to the more general setting.

Let $\mathcal{A}_1 = (S_1, S_1^0, \operatorname{Tran}_1)$, $\mathcal{A}_2 = (S_2, S_2^0, \operatorname{Tran}_2)$ be NAA and define $\mathcal{A}_1/\mathcal{A}_2 = (S, S^0, \operatorname{Tran})$, with $S = 2^{S_1 \times S_2}$. To define the set of initial states, let us first enumerate the initial states of \mathcal{A}_2 as follows: $S_2^0 = \{s_2^{0,1}, \dots, s_2^{0,p}\}$. The set of initial states is given by all possible assignments of states from S_1^0 to states of S_2^0 , formally: $S^0 = \{\{(s_1^{0,q}, s_2^{0,q}) \mid q \in \{1, \dots, p\}\} \mid \forall q : s_1^{0,q} \in S_1^0\}$.

The assignment of transition constraints Tran is given as follows. Let $\operatorname{Tran}(\emptyset) = 2^{\Sigma \times \{\emptyset\}}$. For $s = \{(s_1^1, s_2^1), \dots, (s_1^n, s_2^n)\} \in S$, say that $a \in \Sigma$ is permissible from s if it holds for all $i = 1, \dots, n$ that there is $M_1 \in \operatorname{Tran}_1(s_1^i)$ and $t_1 \in S_1$ for which $(a, t_1) \in M_1$, or else there is no $M_2 \in \operatorname{Tran}_2(s_2^i)$ and $t_2 \in S_2$ with $(a, t_2) \in M_2$.

Let us now fix a nonempty $s = \{(s_1^1, s_2^1), \dots, (s_1^n, s_2^n)\} \in S$. We introduce some notation that we are going to use throughout this construction and the following proof to denote the successor states of s_2^i for all i. For each s_2^i let $\operatorname{Tran}_2(s_2^i) = \{M_2^{i,1}, \dots, M_2^{i,m_i}\}$ be a fixed enumeration of $\operatorname{Tran}_2(s_2^i)$. For each a permissible from s and for each $M_2^{i,j}$ we further fix an enumeration of all states in $M_2^{i,j}$ after an a-transition: $\{t_2 \in S_2 \mid (a,t_2) \in M_2^{i,j}\} = \{t^{i,j,a,1}, \dots, t^{i,j,a,r_{i,j,a}}\}$. This means that $t^{i,j,a,k}$ is the kth state (out of t^i), which is the t^i th member of $\operatorname{Tran}_2(s_2^i)$, where t^i is the state in the t^i th pair in t^i

For a permissible from s, we define

$$pt_a(s) = \left\{ \left\{ \left\{ \left(t_1^{i,j,a,k}, i, j, t_2^{i,j,a,k} \right) \mid i = 1, \dots, n, j = 1, \dots, m_i, k = 1, \dots, r_{i,j,a} \right\} \right. \\ \forall i, j, k : \exists M_1 \in \text{Tran}_1(s_1^i) : (a, t_1^{i,j,a,k}) \in M_1 \right\},$$

the set of all sets of possible assignments of next-a states from s_1^i to next-a states from s_2^i . Note that unlike the case of MTS quotient, we also keep the indices i, j in the assignments. We further define $pt(s) = \{(a, x) \mid a \text{ permissible from } s, x \in pt_a(s)\}$.

To deal with the elements of $pt_a(s)$ we define the following auxiliary operations. The first operation ℓ allows us to "forget" the indices i, j and is defined as follows: $\ell(x) = \{(t_1, t_2) \mid \exists i, j : (t_1, i, j, t_2) \in x\}$. The operation can be naturally lifted to subsets of pt(s) as follows: $\ell(N) = \{(a, \ell(x)) \mid (a, x) \in N\}$ where $N \subseteq pt(s)$.

The second operation is a type of projection that given the two indices i, j and the state $t_2^{i,j,a,k}$ produces the next-a state of s_1 assigned in the given element x

of $pt_a(s)$. Note that the projection is defined uniquely: $x \upharpoonright (i,j,t_2^{i,j,a,k}) = t_1^{i,j,a,k}$ where $x = \{\ldots,(t_1^{i,j,a,k},i,j,t_2^{i,j,a,k}),\ldots\}$. The projection operation can also be lifted to subsets N of pt(s) and sets $M_2 \in \operatorname{Tran}_2(s_i^2)$ as follows: $N \upharpoonright (i,j,M_2) = \{(a,x \upharpoonright (i,j,t_2)) \mid (a,t_2) \in M_2\}$. Note that the result of this operation is then a set of elements of the form (a,t_3) where t_3 is an a-successor of s_3 .

Having the two auxiliary operations, we can then finally define

$$\operatorname{Tran}(s) = \{ \ell(N) \mid N \subseteq pt(s), \forall i \in \{1, \dots, n\}, j \in \{1, \dots, m_j\} : \\ N \upharpoonright (i, j, M_2^{i,j}) \in \operatorname{Tran}_3(s_3^i) \}.$$
 (9)

Theorem 27. For all specifications S_1 , S_2 , S_3 , $S_1 || S_2 \leq_m S_3$ iff $S_2 \leq_m S_3 / S_1$.

PROOF. We show the proof for NAA. Let $\mathcal{A}_1 = (S_1, S_1^0, \operatorname{Tran}_1)$ and $\mathcal{A}_2 = (S_2, S_2^0, \operatorname{Tran}_2)$, $\mathcal{A}_3 = (S_3, S_3^0, \operatorname{Tran}_3)$; we show that $\mathcal{A}_1 \| \mathcal{A}_2 \leq_{\mathsf{m}} \mathcal{A}_3$ iff $\mathcal{A}_2 \leq_{\mathsf{m}} \mathcal{A}_3 / \mathcal{A}_1$.

We use the notation introduced in the proof of Theorem 26, i.e. $s_1||s_2$ instead of (s_1, s_2) when speaking about states of $\mathcal{A}_1||\mathcal{A}_2$ and $\{s_3/s_1, \ldots\}$ instead of $\{(s_3, s_1), \ldots\}$ when speaking about states of $\mathcal{A}_3/\mathcal{A}_1$. We further note that by construction, $s \supseteq t$ implies $s \subseteq_{\mathsf{m}} t$ for all $s, t \in 2^{S_3 \times S_1}$.

Now assume that $\mathcal{A}_2 \leq_{\mathsf{m}} \mathcal{A}_3/\mathcal{A}_1$ and let $R = \{(s_1 \| s_2, s_3) \mid s_2 \leq_{\mathsf{m}} \{s_3/s_1\}\};$ we show that R is a witness for $\mathcal{A}_1 \| \mathcal{A}_2 \leq_{\mathsf{m}} \mathcal{A}_3$.

Let $(s_1||s_2,s_3) \in R$ and $M_{\parallel} \in \operatorname{Tran}_{\parallel}(s_1||s_2)$. Then $M_{\parallel} = M_1||M_2$ with $M_1 \in \operatorname{Tran}_1(s_1)$ and $M_2 \in \operatorname{Tran}_2(s_2)$. As $s_2 \leq_{\mathfrak{m}} \{s_3/s_1\}$, we can pair M_2 with an $M_{/} \in \operatorname{Tran}_{/}(\{s_3/s_1\})$, such that the conditions in (2) are satisfied (see Definition 7).

Note that, as $M_1 \in \text{Tran}_1(s_1)$, there exists some j such that $M_1 = M_1^{1,j}$, *i.e.* M_1 is the jth element of $\text{Tran}(s_1)$ in the enumeration as described in the construction of the quotient. Further note that $M_{\parallel} = \ell(N)$ for some $N \subseteq pt(\{s_3/s_1\})$ satisfying the conditions in (9).

We now define $M_3 = N \upharpoonright (1, j, M_1)$ and show that (2) holds for the pair M_{\parallel}, M_3 :

- Let $(a, t_1 || t_2) \in M_{\parallel}$, then there are $(a, t_1) \in M_1$ and $(a, t_2) \in M_2$. By (2) applied to the pair M_2 , $M_{/}$, there is $(a, t) \in M_{/}$ such that $t_2 \leq_{\mathsf{m}} t$. This means that there is $(a, x) \in N$ such that $t = \ell(x)$. Due to the construction of $pt(\{s_3/s_1\})$ there has to be some t_3 such that $(t_3, 1, j, t_1) \in x$. Due to the definition of M_3 , this means that $(a, t_3) \in M_3$. We also know that $t \supseteq \{t_3/t_1\}$, hence $t \leq_{\mathsf{m}} \{t_3/t_1\}$, and together with $t_2 \leq_{\mathsf{m}} t$ we get $t_2 \leq_{\mathsf{m}} \{t_3/t_1\}$. Thus $(t_1 || t_2, t_3) \in R$.
- Let $(a,t_3) \in M_3$. This means that there is some $(a,x) \in N$ with $(t_3,1,j,t_1) \in x$ and $(a,t_1) \in M_1$. Therefore, $\ell(x) = t \in M_f$ with $t_3/t_1 \in t$. Due to (2) applied to M_2, M_f , there has to be a corresponding $(a,t_2) \in M_2$ such that $t_2 \leq_{\mathsf{m}} t$. Thus $(a,t_1\|t_2) \in M_{\|}$ and again by $t \supseteq \{t_3/t_1\}$ we have $t_2 \leq_{\mathsf{m}} \{t_3/t_1\}$ and hence $(t_1\|t_2,t_3) \in R$.

It remains to show that R is initialised. Let $\hat{s}_1^0 \| \hat{s}_2^0$ be an initial state of $\mathcal{A}_1 \| \mathcal{A}_2$. By $\mathcal{A}_2 \leq_{\mathsf{m}} \mathcal{A}_3 / \mathcal{A}_1$ we know that $\hat{s}_2^0 \leq_{\mathsf{m}} s^0$ for some $s^0 \in S^0$. We then take $\hat{s}_3^0 \in S_3^0$ such that $\hat{s}_3^0 / \hat{s}_1^0 \in s^0$ (there has to be exactly one due to the definition of s^0). We then have $s^0 \supseteq \{\hat{s}_3^0 / \hat{s}_1^0\}$ and thus $s^0 \leq_{\mathsf{m}} \{\hat{s}_3^0 / \hat{s}_1^0\}$. This means that $\hat{s}_2^0 \leq_{\mathsf{m}} \{\hat{s}_3^0 / \hat{s}_1^0\}$ and hence $(\hat{s}_1^0 \| \hat{s}_2^0, \hat{s}_3^0) \in R$.

Assume, for the other direction of the proof, that $A_1 \| A_2 \leq_{\mathsf{m}} A_3$. Define $R \subseteq S_2 \times 2^{S_3 \times S_1}$ by

$$R = \{(s_2, \{s_3^1/s_1^1, \dots, s_3^n/s_1^n\}) \mid \forall i = 1, \dots, n : s_1^i | | s_2 \leq_{\mathsf{m}} s_3^i \};$$

we show that R is a witness for $A_2 \leq_{\mathsf{m}} A_3/A_1$. We first note that $(s_2,\emptyset) \in R$ for all s_2 . Let now $(s_2,s) \in R$, with nonempty $s = \{s_3^1/s_1^1, \ldots, s_3^n/s_1^n\}$, and $M_2 \in \operatorname{Tran}_2(s_2)$.

Note that for every $M_1^{i,j} \in \text{Tran}(s_1^i)$ we can build $M_{\parallel}^{i,j} = M_1^{i,j} \| M_2$, and as $s_1^i \| s_2 \leq_{\text{m}} s_3^i$, there has to be a corresponding $M_3 \in \text{Tran}(s_3^i)$ satisfying the conditions of (2). We fix such M_3 for every i, j and denote it by $M_3^{i,j}$.

We are going to build a subset N of pt(s). To that end, we first define an auxiliary notion of an adequate element of pt(s) with respect to $(a,t_2) \in M_2$ as follows. Let $(a,x) \in pt(s)$. We say that (a,x) is adequate w.r.t. (a,t_2) if for every $i \in \{1,\ldots,n\}, \ j \in \{1,\ldots,m_i\}, \ \text{and} \ k \in \{1,\ldots,r_{i,j,a}\}, \ \text{the projection} \ t_3 = x \upharpoonright (i,j,t_1^{i,j,k}) \ \text{satisfies} \ (a,t_3) \in M_3^{i,j} \ \text{and} \ t_1^{i,j,k} \| t_2 \leq_{\mathsf{m}} t_3.$

Clearly, if we have (a, x) adequate w.r.t. (a, t_2) , then $(t_2, \ell(x)) \in R$. We can now define

$$N = \{(a, x) \in pt(s) \mid \exists (a, t_2) \in M_2 : (a, x) \text{ is adequate w.r.t. } (a, t_2) \}.$$

We first need to show that $\ell(N) \in \operatorname{Tran}_{/}(s)$. Let $i \in \{1,\ldots,n\}$ and $j \in \{1,\ldots,m_j\}$. We want to show that $N \upharpoonright (i,j,M_1^{i,j}) = M_3^{i,j}$. Let first $(a,t_3) \in N \upharpoonright (i,j,M_1^{i,j})$. This means that there is some $(a,x) \in N$ with $x = (t_3,i,j,t_1^{i,j,k})$. Due to the definition of $N, (a,t_3) \in M_3^{i,j}$. Let now $(a,t_3) \in M_3^{i,j}$. Recall that the pair $M_1^{i,j} \| M_2, M_3^{i,j}$ satisfies (2). This means that for $(a,t_3) \in M_3^{i,j}$ there exists $(a,t_1^{i,j,k} \| t_2) \in M_1^{i,j} \| M_2$ such that $t_1^{i,j,k} \| t_2 \leq_{\operatorname{m}} t_3$. Hence $(a,(t_3,i,j,t_1^{i,j,k}))$ is adequate w.r.t. (a,t_2) and thus $(a,t_3) \in N \upharpoonright (i,j,M_1^{i,j})$.

We now show that the pair M_2 , $M = \ell(N)$ satisfies the conditions of (2).

- Let $(a,t_2) \in M_2$. We need to show that there exists $(a,x) \in N$ adequate w.r.t. (a,t_2) . Recall that the pair $M_1^{i,j} \| M_2$, $M_3^{i,j}$ satisfies (2) for every i,j. For every $(a,t_1^{i,j,k} \| t_2)$ there thus has to be $(a,t_3) \in M_3^{i,j}$ with $t_1^{i,j,k} \| t_2 \leq_m t_3$. We fix such t_3 for every i,j,k and denote it by $t_3^{i,j,k}$. We then set $x = \{(t_3^{i,j,k},i,j,t_1^{i,j,k} \mid i \in \{1,\ldots,n\}, j \in \{1,\ldots,m_i\}, k \in \{1,\ldots,r_{i,j,a}\}$. Clearly $(a,x) \in N$ and (a,x) is adequate w.r.t. (a,t_2) . As noted above, we have $(t_2,\ell(x)) \in R$.
- Let $(a,t) \in M$. This means that there is some $(a,x) \in N$ such that $t = \ell(x)$. Due to the definition of N, there exists $(a,t_2) \in M_2$ such that (a,x) is adequate w.r.t. (a,t_2) . Again, as noted above, we have $(t_2,t)=(t_2,\ell(x))\in R$.

It remains to show that R is initialised. Let s_2^0 be an initial state of \mathcal{A}_2 . By $\mathcal{A}_1 \| \mathcal{A}_2 \leq_{\mathsf{m}} \mathcal{A}_3$ we know that for every $s_1^{0,q} \in S_1^0$ (recall the enumeration of initial states in the construction of the quotient) there exists $s_3^0 \in S_3^0$ such that $s_1^{0,q} \| s_2^0 \leq_{\mathsf{m}} s_3^0$. Let us fix for every q such s_3^0 and denote it by $s_3^{0,q}$. Let then $s^0 = \{s_3^{0,q}/s_1^{0,q} \mid q \in \{1,\ldots,p\}\}$. Clearly, s^0 is an initial state of $\mathcal{A}_3/\mathcal{A}_1$ and $(s_2^0,s^0) \in R$.

As a corollary, we get (8): If $\mathcal{I}_2 \in [\![\mathcal{S}/\mathcal{S}_1]\!]$, i.e. $\mathcal{I}_2 \leq_m \mathcal{S}/\mathcal{S}_1$, then $\mathcal{S}_1 \| \mathcal{I}_2 \leq_m \mathcal{S}$, which using $\mathcal{I}_1 \leq_m \mathcal{S}_1$ and Theorem 24 implies $\mathcal{I}_1 \| \mathcal{I}_2 \leq_m \mathcal{S}_1 \| \mathcal{I}_2 \leq_m \mathcal{S}$. The reverse implication in Theorem 27 implies that $\mathcal{S}/\mathcal{S}_1$ is as permissive as possible.

Corollary 28. With operations \land , \lor , \parallel and \backslash , each of our four classes of specifications forms a commutative residuated lattice up to \equiv_m .

PROOF. We have already seen in Corollary 21 that the class of NAA forms a lattice, up to \equiv_m , under \wedge and \vee , and by Theorem 27, / is the residual, up to \equiv_m , of \parallel . All other properties (such as distributivity of \parallel over \vee or $\mathcal{N}\parallel\perp\equiv_m\perp$) follow.

5. Related Work

The modal ν -calculus is equivalent to the Hennessy-Milner logic with greatest fixed points, which arises from Hennessy-Milner logic (HML) [34] by introducing variables and greatest fixed points. If also least fixed points are allowed, one arrives at the full modal μ -calculus [36, 48, 56]. Janin and Walukiewicz have in [35] introduced an automata-like representation for the modal μ -calculus which seems related to our NAA.

DMTS have been proposed as solutions to algebraic process equations in Larsen and Xinxin's [44] and further investigated also as a specification formalism [7, 41]. The DMTS formalism is a member of the modal transition systems (MTS) family and as such has also received attention recently. The MTS formalisms have proven to be useful in practice. Industrial applications started with Bruns' [16] where MTS have been used for an air-traffic system at Heathrow airport. Besides, MTS classes are advocated as an appropriate base for interface theories by Raclet et al. in [53] and for product line theories in Nyman's [46]. Further, an MTS based software engineering methodology for design via merging partial descriptions of behaviour has been established by Uchitel and Chechik in [57] and methods for supervisory control of MTS shown by Darondeau et al. in [22]. Tool support is quite extensive, e.g. [6, 14, 23, 39].

Over the years, many extensions of MTS have been proposed, surveyed in more detail in [24, 25, 38]. While MTS can only specify whether or not a particular transition is required, some extensions equip MTS with more general abilities to describe what *combinations* of transitions are possible. These include DMTS [44], Fecher and Schmidt's 1-MTS [27] allowing to express exclusive disjunction, OTS [11] capable of expressing positive Boolean combinations, and Boolean MTS [9] covering all Boolean combinations. The last one is closely related to our NAA as well as hybrid modal logic [13, 49]. Our results show that all these formalisms are at most as expressive as DMTS.

Larsen has shown in [40] that any finite acyclic MTS is equivalent to a HML formula (without recursion or fixed points), the *characteristic formula* of the given MTS, cf. (3). Conversely, Boudol and Larsen show in [15] that any consistent and *prime* HML formula is equivalent to a MTS.⁷ Here we extend these results to ν -calculus formulae, and show that any such formula is equivalent to a DMTS, solving a problem left open in [44]. Hence the modal ν -calculus supports

⁷A HML formula is *prime* if implying a disjunction means implying one of the alternatives.

full compositionality and decomposition in the sense of [41]. This finishes some of the work started in [15, 40, 41]. Recently, the graphical representability of a variant of alternating simulation called covariant-contravariant simulation has been studied in [1].

Quotients are related to decomposition of processes and properties, an issue which has received considerable attention through the years. In [44], a solution to bisimulation $C(X) \sim P$ for a given process P and context C is provided (as a DMTS). This solves the quotienting problem P/C for the special case where both P and C are processes. This is extended in [43] to the setting where the context C can have several holes and $C(X_1, \ldots, X_n)$ must satisfy a ν -calculus property Q. However, C remains to be a process context, not a specification context. Our specification context allows for arbitrary specifications, representing infinite sets of processes and process equations. Other extensions use infinite conjunctions [29], probabilistic processes [30] or processes with continuous time and space [20].

Quotient operators, or guarantee or multiplicative implication as they are called there, are also well-known from various logical formalisms. Indeed, the algebraic properties of our parallel composition \parallel and quotient / resemble closely those of multiplicative conjunction & and implication \multimap in linear logic [31], and of spatial conjunction and implication in spatial logic [19] and separation logic [47, 54]. For these and other logics, proof systems have been developed which allow one to reason about expressions containing these operators. In these logics, & and \multimap are first-class operators on par with the other logical operators, and their semantics are defined as certain sets of processes. In contrast, for NAA and hence, via the translations, also for ν -calculus, \parallel and / are derived operators, and we provide constructions to reduce any expression which contains them, to one which does not. This is important from the perspective of reuse of components and useful in industrial applications. To the best of our knowledge, there are no other such reductions of quotient for the synchronisation type of composition in the context of specifications.

6. Conclusion

In this paper we have introduced a general specification framework whose basis consists of four different but equally expressive formalisms: one of a graphical behavioural kind (DMTS), one logic-based (ν -calculus) and two intermediate languages between the former two (NAA and hybrid modal logic). We have shown their structural equivalence.

The established connection implies several consequences. On the one hand, it allows for a graphical representation of ν -calculus. Further, composition on DMTS can be transferred to the modal ν -calculus, hence turning it into a modal process algebra. On the other hand, such a correspondence identifies a class of modal transition systems with a natural expressive power and provides another justification of this formalism. Further, this class is closed under both conjunction and disjunction, a requirement raised by component-based design methods. However, it is not closed under complement and difference.⁸ Nevertheless, since

⁸Previous results on difference [55] are incorrect due to a mistake in [28] on conjunction of MTS, see [37, p. 36].

DMTS are closed under conjunction, disjunction and composition, we still have a positive Boolean process algebra.

Altogether, we have shown that the framework possesses a rich algebraic structure that includes logical (conjunction, disjunction) and behavioural operations (parallel composition and quotient) and forms a complete specification theory in the sense of [4, 41].

Moreover, the construction of the quotient solves an open problem in the area of MTS. All attempts to find the quotient for variants of MTS so far have been limited to the much simpler deterministic case [52]. Here we have given the first solution to the quotient on nondeterministic specifications: first, a quotient construction for MTS, and then a quotient for general DMTS. Due to the established correspondence, the quotient can be applied also to ν -calculus formulae. We remark that all our translations and constructions are based on a new normal form for ν -calculus expressions, and that turning a ν -calculus expression into normal form may incur an exponential blow-up. However, the translations and constructions preserve the normal form, so that this translation only need be applied once in the beginning.

As for future work, we hope to establish the exact complexity of the quotient constructions. We conjecture that the exponential blow-up of the construction is in general unavoidable. Further, we plan to implement the operations detailed here within the graphical tool MoTraS [39].
